GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by the Franklin Institute Press^{SM}.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 15, consisting of 12 monthly issues and a cumulative index is $75.00, Domestic and $90.00, Foreign. Check should be made payable to The Franklin Institute Press.

Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

GENERAL INFORMATION

RCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer ticles collected from the current major biomedical sources of the world literature. This service is provided by e National Cancer Institute through a contract with Franklin Research Center for preparation of the blication.

REQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 15, is published in 12 onthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

URNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation sting*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title ord Abbreviations.*

NGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. e source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

BBREVIATIONS used in abstracts:

	angstrom(s)	mOsm	milliosmolar
CTH	adrenocorticotropic hormone	max	maximum
DP	adenosine diphosphate	mEq	milliequivalent(s)
MP	adenosine monophosphate	min	minute(s)
TP	adenosine triphosphate	ml	milliliter(s)
prox	approximately	µl	microliter(s)
	average	mm	millimeter(s)
CG	bacillus Calmette-Guerin	mo	month(s)
d	twice daily	mol wt	molecular weight

M	micromolar	yr	year(s)

8-2401 **Carcinogenic Potential of Cancer Chemotherapeutic Agents in Man.** (Eng) Adamson, R. I. (Lab. Chemical Pharmacology, Div. Cancer Treatment, NCI, Bethesda, MD, 20014); Sieber, S. M. *Cancer Bull* 29(6): 79-183; 1977.

Case studies have indicated that many alkylating agents, anitumor antibiotics, and antitumor antimetabolites used in the reatment of both malignant and nonmalignant conditions an be carcinogenic. It is suggested that a Second Tumor Registry be established to assess the carcinogenic potential of these agents. This registry would contain information on hemotherapy and other treatment, the patient, and the size of the population receiving similar treatment. (7 refs)

'8-2402 **Dangers of Oversimplification in the Tier Approach (Meeting Abstract).** (Eng) Russell, W. L. Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830). *Autat Res* 53(1): 104; 1978. (no refs)

'8-2403 **In Vivo DNA Damage/Alkaline Elution Assay for Predicting Carcinogenic Potential (Meeting Abstract).** (Eng) Petzold, G. (Upjohn Co., Kalamazoo, MI, 9001); Harbach, P.; Bedell, M.; Swenberg, J. A. *Mutat Res* 3(1): 110-111; 1978. (no refs)

'8-2404 **Evidence Against the Reversion of Mutation in the *Haemophilus Influenzae* Phage HP1c1 by Preinfection Treatment of Host Cells or Phage with MNNG.** Eng) Boling, M. E. (Biology Div., Oak Ridge Lab., Oak Ridge, TN, 37830); Kimball, R. F. *Mutat Res* 50(1): 37-42; 978.

The mutagenic effects of N-methyl-N′-nitro-N-nitrosoguaniline (MNNG) on the temperature-sensitive *Haemophilus influenzae* phage HP1c1 were studied. Phage DNA and uninfected cells were treated with MNNG (50 or 100 μg/ml) at) C and then combined. Cells treated with MNNG after ransfection served as a positive control. No mutations were nduced when the bacteria and/or phage DNA were treated with MNNG before transfection. In contrast, when phage DNA was treated inside the host cell, a high frequency of reversion was observed. Thus, there is no evidence that treatment of bacteria with MNNG induces alterations in the bacteria that can produce mutations in either untreated DNA or DNA treated separately before transfection. It is likely that the initial lesions in the DNA are eliminated during transformation either by repair or by a failure to be incorporated into the host genome. (17 refs)

78-2405 **Approaches to Determining the Mutagenic Properties of Chemicals: Risk to Future Generations.** (Eng) DHEW Working Group Subcommittee Environmental Mutagenesis (No affiliation given). *Environ Pathol Toxicol* 1(2): 301-352; 1977.

There are three objectives for mutagenicity testing of chemicals: (1) to determine whether a chemical has the potential to cause heritable genetic changes in humans; (2) to obtain data from animal model systems for which safe exposure levels for humans may be extrapolated; and (3) to provide information on other toxicological manifestations, such as carcinogenicity. Factors to be considered in designing a test strategy include the use and exposure category of the test substances, stage of development of a product, existing and anticipated levels of human exposure, legislative aspects, regulatory status, and available resources for testing. Procedures necessary to define a chemical as a human mutagen include tests that detect chromosome and point mutations. In evaluating chromosomal effects, either the heritable translocation test or the sex chromosome loss test in mice can provide sufficient evidence. For evaluating point mutations, the only mammalian test available that can provide sufficient evidence in itself is the specific locus test in mice. As an alternative, positive results in 2/3 following categories should be considered evidence of mutagenicity: point mutations in eukaryotic microorganisms or in mammalian cells in cultures and recessive lethal mutations in insects. The current mutagenicity testing experience of various classes of chemicals is illustrated in an extensive table. (90 refs)

78-2406 **Does Carcinogenic Potency Correlate with Mutagenic Potency in the Ames Assay?** (Eng) Ames, B. N. (Dept. Biochemistry, Univ. California, Berkeley, CA, 94720); Hooper, K. *Nature* 274(5666): 19-20; 1978.

Reply is made to criticism of current research in which the relation between the potency of a chemical in an animal cancer test and in the *Salmonella typhimurium* mutagenicity assay was explored. Given the millionfold range in carcinogenic and mutagenic potencies, correspondence between the two can be useful without needing to be very precise. Several literature reports indicate that there is a good correlation for most chemicals examined so far. In addition, other short-term tests seem to show responses similar to that of *Salmonella*. It is true that varying the standard test parameters could change the potency somewhat and that there is a problem of false negatives/positives, but some carcinogens will never be detected in the *Salmonella* test because they cause cancer by nonmutagenic mechanisms or for other reasons. However, many short-term tests, including the *Salmonella* assay, have successfully predicted carcinogenicity for several environmental chemicals with widespread human exposure (ie, tris, 1,2-dichloroethane, hair dye chemicals). It is expected that a battery of short-term tests will soon be useful in estimating carcinogenic potency as well. (14 refs)

78-2407 **Use of Purified Lesion-Recognizing Enzymes to Monitor DNA Repair in Vivo.** (Eng) Paterson, M. C. (Biology and Health Physics Div., Chalk River Nuclear Lab., Atomic Energy of Canada Limited, Chalk River, Ontario, Canada). *Adv Radiat Biol* 7: 1-53; 1978.

This review deals with a recent methodological advance, exploitation of the unique properties of purified lesion-recognizing enzymes as the basis of assays that monitor, with a high degree of sensitivity and specificity, the repair of DNA lesions in vivo. The enzymes include UV endonucleases, apurinic site endonucleases and N-glycosidases, and γ-endonucleases. The assays are described in detail, their assets and liabilities are weighed, and new findings emerging from their use are presented. (178 refs)

78-2408 **Environmental Carcinogenesis (Meeting Abstract).** (Eng) Falk, H. L. (Natl. Inst. Environmental Sciences, Research Triangle Park, NC). *Clin Chem* 24(6): 971-972; 1978. (no refs)

78-2409 **Experimental Identification of Chemical Carcinogens, Risk Evaluation, and Animal-to-Human Correlations.** (Eng) Saffiotti, U. (Experimental Pathology Branch, NCI, NIH, Bethesda, MD, 20014). *Environ Health Perspect* 22: 107-113; 1978.

Experimental methods for the identification of chemical carcinogens include animal bioassay methods, animal models for cancer induction at major organ sites, models for the study of the effects of carcinogens in cells and tissues in culture, and methods for the study of molecular events. The following steps are necessary for the evaluation of risks, benefits, and technological alternatives for public policy on environmental carcinogens: (1) risk evaluation, which should consider sources, adequacy, quality and limits of the evidence, quantitative dose-response extrapolation within the same biological system, and species and model conversion factors; (2) benefit evaluation; (3) analysis of technological alternatives to identify the estimated least hazardous technological alternative and to determine its feasibility; (4) comparative judgement and decision; and (5) open public documentation. The problem of animal-to-human correlations is centered on bridging the gap between whole-animal experiments and human pathology. A laboratory approach has been developed, with particular emphasis on respiratory tract carcinogenesis studies, which includes development and study of whole animal models for carcinogenesis, analysis of animal tissue responses to carcinogens in vivo and in vitro and development of in vitro culture methods to study human target tissues and correlation of the results with human pathology in vivo. (64 refs)

78-2410 **Mechanisms of Chemical Carcinogenesis.** (Eng) Weisburger, E. K. (Carcinogen Metabolism and Toxicology Branch, NCI, Bethesda, MD, 20014). *Annu Rev Pharmacol Toxicol* 18: 395-415; 1978.

The mechanisms of action of chemical carcinogens, their metabolic activation, and the influence of other xenobiotics on carcinogens are reviewed. Most chemical carcinogens are initially converted through mixed function oxidases to activated forms. Further reaction leads to entities, often transient, that are electrophiles capable of reacting with cellular nucleophiles. Other environmental factors may enhance or inhibit the action of carcinogens. (211 refs)

78-2411 **Metals as Mutagens.** (Eng) Flessel, C. P. (Biochemistry Group, Air and Industrial Hygiene Lab., State California, Dept. Health, 2151 Berkeley Way, Berkeley, CA). *Adv Exp Med Biol* 91: 117-128; 1977.

Evidence that compounds of arsenic, chromium, copper, iron, manganese, molybdenum, platinum, and selenium are mutagenic in microorganisms is presented. In addition, compounds of aluminum, antimony, arsenic, cadmium, copper, lead, mercury, nickel, and tellurium induce chromosome damage in higher organisms. Of these metals, arsenic, cadmium, chromium, iron, lead, manganese, and nickel are reportedly carcinogenic in animals or humans. In contrast, selenium and platinum have been described as cancer-protecting or carcinostatic agents, respectively. (44 refs.)

78-2412 **Occupational Exposure to Inorganic Arsenic.** (Eng) Brinkerhoff, G. (Office Compliance Programs, Occupational Safety and Health Administration, Room N-3112, Third St. and Constitution Ave., N. W., Washington, DC, 20210). *Fed Regist* 43(88): 19584-19631; 1978.

The Occupational Safety and Health Administration's ruling on inorganic arsenic exposure in the workplace is presented, along with the evidence on which the ruling is based. Occupational exposure to inorganic As is limited to 10 $\mu g/m^3$ based on an 8-hr time-weighted av. The evidence indicates that inorganic As exposure causes lung cancer, with the risk increasing with exposure. Pentavalent As should be regulated as a human carcinogen. (29 refs)

78-2413 **Talc in Drugs (Letter to Editor).** (Eng) Nicar, M. J. (Health Science Center at Dallas, Southwestern Medical Sch., Univ. Texas, Dallas, TX, 75235); Norman, D. A. *N Engl J Med* 299(10): 556-557; 1978.

Although several pharmaceutical drugs contain talc, which is chemically similar to asbestos, no experimental data have shown that ingestion of talc or asbestos causes cancer. The carcinogenicity of asbestos seems limited to inhaled asbestos. Therefore, there should be more immediate concern for pharmaceutical employees who might inhale talc rather than for patients who take these drugs. (6 refs.)

78-2414 **The Biological Effects of Talc in the Experimental Animal: A Literature Review.** (Eng) Lord, G. H. (Johnson and Johnson Res. Foundation, New Brunswick, NJ). *Food Cosmet Toxicol* 16(1): 51-57; 1978.

Literature on the exposure of experimental animals to talc is reviewed. Although the talcs used have not been characterized, it has been shown that the mineral, in different degrees of purity, is fibrogenic and that the fibrotic response is a function of dose. However, certain levels of exposure are tolerable. No neoplastic response has been observed. (41 refs)

78-2415 **Toxicology of Vinyl Chloride.** (Fre) Heuse, A. (Laboratoire de Medecine du Travail et Hygiene du Milieu, Universite Libre de Bruxelles, Brussels, Belgium). *Brux Med* 58(1): 13-34; 1978.

A review of the literature on vinyl chloride (VC) traces the history of the toxicity of the compound. Also reviewed are the toxic effects of polyvinyl chloride (PVC), relative risk of industrial exposure to VC and PVC, and potential danger of exposure of the general population to PVC. (196 refs)

78-2416 **Dechlorination Mechanisms of Chlorinated Olefins.** (Eng) Van Dyke, R. A. (Mayo Clinic, Rochester, MN, 55901). *Environ Health Perspect* 21: 121-124; 1977.

The dechlorination of chlorinated hydrocarbons were investigated in detail. The reaction occurs optimally in the presence of O_2 and it is catalyzed by Cytochrome P-450. The oxidative dechlorination of hydrocarbons begins by an attack on the C atom and the halogen is then released from the oxidized C. Chlorinated olefins are not easily dechlorinated enzymatically. Since the chlorines migrate readily across the double bond, cyclic chloronium ions must occur as intermediates. It is not known if an epoxide is a necessary intermediate for chloronium ion formation. (22 refs)

78-2417 **Oncogenic Transformation of Rodent Cell Lines by Chemical Carcinogens.** (Eng) Heidelberger, C. (Los Angeles County-Univ. Southern California Cancer Center, Los Angeles, CA, 90031). *In: Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H., Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. 4(Book C), 583 pp.; 1513-1520; 1977.

Experimental studies of the chemical transformation of mouse prostate fibroblasts and mouse embryo C3H/10T1/2 cells are reviewed. If these lines can be transformed by representative compounds from various classes of chemical carcinogens, they will be of value as prescreens for environmental carcinogens. (78 refs.)

78-2418 **Evaluation of the Health Effects of Benzene Inhalation.** (Eng) Haley, T. J. (Dept. Health, Education and Welfare, Food and Drug Admin., Natl. Center Toxicological Res., Jefferson, AR, 72079). *Clin Toxicol* 11(5): 531-548; 1977.

Animal and human data on the acute and chronic toxicity, absorption, distribution, metabolism, and excretion of benzene are reviewed. Benzene exposure produces hypoplasia of the bone marrow, which leads to aplastic anemia; chronic exposure, either occupationally or domestically, can cause leukemia. (100 refs)

78-2419 **The Metabolism of Polycyclic Hydrocarbons and Its Relationship to Cancer.** (Eng) DePierre, J. W. (Dept. Biochemistry, Arrhenius Lab., Univ. Stockholm, Fack, S-106 91, Stockholm, Sweden); Ernster, L. *Biochim Biophys Acta* 473(3/4): 149-186; 1978.

The metabolism of polycyclic hydrocarbons in rat liver and lung and in various human tissues is reviewed in relation to the carcinogenic properties of these compounds. The major pathways for the metabolism of polycyclic hydrocarbons in mammalian tissues involve the aryl hydrocarbon monooxygenase system, epoxide hydrase, and glutathione S-epoxide transferase. There is much evidence to support the hypothesis that epoxide intermediates formed by aryl hydrocarbon monooxygenase activity react nonenzymatically with DNA and are the immediate carcinogens. Although the exact mechanism of polycyclic hydrocarbon carcinogenesis is not known, correlations between aryl hydrocarbon monooxygenase and cancer have been found. The inducibility of aryl hydrocarbon monooxygenase in human peripheral lymphocytes was shown in one study to be controlled genetically by two alleles, A and B; cells containing AA had low inducibility, AB medium inducibility, and BB high inducibility. A study of 50 smokers with bronchial cancer revealed that 4%

had AA, 66% AB, and 30% BB compared with normal US incidences of 45% for AA, 46% for AB, and 9.4% for BB. It is also becoming clearer that smoking induces aryl hydrocarbon monooxygenase activity in lung cells. In one study, smokers (10-40 cigarettes/day for at least 2 yr) were found to have aryl hydrocarbon monooxygenase levels in their alveolar macrophages that were almost 12 times as high as those of nonsmokers. (426 refs.)

78-2420 **Problems in the Assessment of Human Risk of Carcinogenesis from Chemicals.** (Eng) Weinhouse, S. (Fels Res. Inst., Temple Univ. Sch. Medicine, Philadelphia, PA, 19140). *In: Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4(Book C), 583 pp.; 1307-1309; 1977.

Problems involved in assessing the human risk of carcinogenesis from chemical carcinogens include the extrapolation of animal incidences at high doses to incidences at low doses, extrapolation of animal data (frequently in animals with specific genetic makeup) to humans (diversified genetic makeup), determination of a threshold dose and a latent period, and the significance of negative results of carcinogenesis studies. (4 refs.)

78-2421 **The Value of Long-term Testing for the Implementation of Primary Prevention.** (Eng) Tomatis, L. (Unit Chemical Carcinogenesis, International Agency Res. Cancer, Lyon Cedex 2, France). *In: Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1339-1357; 1977.

The role of experimental animal data in predicting the risk of chemical carcinogenesis in humans is reviewed. Three conditions are necessary for the implementation of primary cancer prevention: (1) cancer is caused by exogenous factors; (2) the factors can be identified; and (3) they can be eliminated once identified. Several examples in which carcinogens were identified in animals before they caused tumors in humans are presented; had the results of the animal studies been taken seriously, cancer prevention could have been implemented sooner in man. The results of long-term animal experiments have made possible the International Agency for Research on Cancer's program for evaluating the carcinogenic risk of chemicals to man. Of the 296 chemicals evaluated so far, 21 are probable human carcinogens. The value of sc testing of a chemical for carcinogenesis in mice has been questioned, but evidence suggests that this is both an appropriate index of carcinogenicity and method of administration. Legislation relating to the prevention of occupational cancer in 14 industrialized countries is reviewed briefly. (47 refs.)

78-2422 **Neoplastic Skin Lesions in Salamanders from a Sewage Lagoon Containing Perylene.** (Eng) Windsor, J. G. (Dept. Chemical Engineering, Massachusetts Inst. Technology, Cambridge, MA, 02139); Laflamme, R. E.; Hites, R. A.; Rose, F. L. *Science* 198(4323): 1280-1281; 1977.

Several sources are proposed for the presence of 300 ppm perylene in a Texas sewage lagoon that may have caused a high incidence of neoplastic skin lesions in tiger salamanders. The most probable one is the diagenesis of terrestrial pigments, but others include a fuel spill from a nearby air force base, dumping of asphalt, use of diesel fuel as a mosquitocide, and jet exhaust. (8 refs)

78-2423 **Mutagenic Studies with Acrylonitrile (Three Letters to Editor).** (Eng) Venitt, S. (Inst. Cancer Res., Royal Cancer Hosp., Chester Beatty Res. Inst., Pollards Wood Res. Station, Chalfont St. Giles, Buckinghamshire, England); Milvy, P. *Mutat Res* 57(1): 107-113; 1978.

A recent article on the mutagenicity of acrylonitrile in several strains of *Salmonella typhimurium* reported positive results, but recalculation of the data indicated that the results were positive but tenuous. In a rebuttal, flaws in the recalculation are pointed out, and it is indicated that the original findings were not disproved. In a reply to the rebuttal, it is stated that a test chemical can be considered mutagenic only if it induces a reproducible, dose-related, and statistically significant increase in mutation frequency over control values. (4 refs)

78-2424 **Endometrial Cancer in Turner's Syndrome Following Long-Term Estrogen Treatment.** (Dan) Nielsen, J. (Cytogenetisk laboratorium, Psykiatrisk hospital i Arhus, Arhus, Denmark); Sorensen, K. *Ugeskr. Laeg.* 140(4): 171-172; 1978.

Nine cases of endometrial carcinoma associated with Turner's syndrome were found in the literature. All the patients had been treated with stilbestrol or diethylstilbestrol for 4-20 yr. However, there is no clear relationship between estrogen treatment and endometrial carcinoma in women with Turner's syndrome. (21 refs.)

78-2425 **Exogenous Estrogen and Endometrial Cancer: A Statistical Problem.** (Eng) Barron, B. A. (Dept. Obstetrics and Gynecology, Columbia Univ., Coll. Physicians and Surgeons, New York, NY). *Contemp Obstet Gynecol* 11(21): 135-142; 1978.

The results of five studies in which estrogen use was found to be associated with endometrial cancer are reviewed. The risk of this cancer in users of estrogen preparations is 3.0-7.9 times greater than the risk among nonusers. The increased incidence appears to be associated with both the duration of use and dosage of the estrogen preparation. In another study, however, it was concluded that the apparent association between endometrial cancer and estrogens was the result of the differential rates of screening between users and nonusers. Three studies had concordant results: for at least a subset of women, the use of exogenous estrogens in the peri- and postmenopausal period may increase their risk of developing endometrial cancer. However, the lesions found in users may be different from those encountered in nonusers. The risk factors and natural history of endometrial cancer are also reviewed. (7 refs)

78-2426 **Estrogen Therapy and Endometrial Carcinoma (Letter to Editor).** (Eng) Cohen, M. H. (Veterans Admin. Hosp., 50 Irving St., NW, Washington, DC, 20422). *Arch Intern Med* 138(4): 526-527; 1978.

Studies indicate that women taking estrogen preparations are at a greater risk than nonusers for the development of endometrial cancer. They also indicate that estrogen therapy for breast cancer may result in endometrial cancer. It is suggested that estrogens are overused and that as low a dose as possible should be given for as short a time as necessary. Regular follow-up of the patient's gynecologic status should be made. (refs)

78-2427 **Do Oral Contraceptives Cause Hepatic Lesions? Appraising the Evidence.** (Eng) Reagan, J. W. (Dept. Pathology, Case Western Reserve Univ., Cleveland, OH). *Contemp Obstet Gynecol* 11(4): 107-112; 1978.

A review of the literature on the association between oral contraceptive use and the development of benign hepatic lesions suggests a relationship, but the actual risk involved has not been established. The risk appears to be related to the duration of therapy and, possibly, to the type of steroid used. The pathology of the different reported lesions is described. Hepatoblastomas and hepatocellular carcinomas are observed in patients exposed to oral contraceptives, but the number of cases is too small to allow any definite conclusions. (18 refs)

78-2428 **The Effects of Estrogens and Oral Contraceptives on Hepatic Function.** (Fre) Leclere, J. (Service d'Endocrinologie et Medecine E, C.H.U. de Nancy, Hopital de Brabois, F 54500 Vandoeuvre-les-Nancy, France). *Ann Endocrinol (Paris)* 38(6): 443-446; 1977.

Since 1973, about 150 reports of hepatic tumors, 24 of which were malignant, have been published in the literature. Usually, the patient has been a young woman using oral contraceptives. The well-established effect of estrogens on hepatic function is reviewed, and the possible carcinogenic role of the contraceptives in the rising incidence of hepatic tumors is discussed. (8 refs)

78-2429 **Hepatic Alterations due to Oral Contraceptives.** (Ger) Roschlau, G. (Pathologisches Institut des Bereichs Medizin, Humboldt-Universitat zu Berlin, Schumannstrasse 20/21, DDR-104 Berlin, E. Germany). *Dtsch Gesundheitsw* 32(48): 2271-2274; 1977.

Hepatic changes observed after the long-term use of oral contraceptives include multiple hyperplasia and malignant hepatocellular carcinoma. Steroids may have an indirect carcinogenic effect due to the inhibition of glutathione-S-transferase. (19 refs)

78-2430 **Transplacental Toxicity of Diethylstilbestrol: A Special Problem in Safety Evaluation.** (Eng) McLachlan, J. A. (Environmental Toxicology Branch, Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC); Dixon, R. L. *In: New Concepts in Safety Evaluation.* Mehlman, M. A.; Shapiro, R. E.; Blumenthal, H., eds. (New York: John Wiley & Sons): Advances in Modern Toxicology, Vol. 1, Part 1, 455 pp. 423-448; 1976.

The transplacental carcinogenicity of diethylstilbestrol (DES; 4,4′-dihydroxy-α,β-diethylstilbene) is reviewed. As early as 1959, an association between neonatal exposure to DES and genital tract abnormalities in female offspring was suggested. Twelve years later, the association of prenatal DES exposure and vaginal clear cell adenocarcinoma in daughters of women who took the preparations was reported. Squamous cell dysplasia and carcinoma in situ of the cervix and vagina have also resulted in prenatally exposed patients. The risk of genital tract tumor development in daughters of treated women is unknown. Although subfertility has been detected in laboratory animals exposed to DES, no adequate studies of humans have been performed. Tumor development in male offspring has not been studied adequately, but at least one report has linked prenatal DES exposure with an increase in prostatic, testicular, and bladder cancer in 10 to 19-yr-old male offspring. Another study found epididymal cysts and prostatic inflammation in utero-exposed men. Early gestational DES exposure appears to be necessary for later development of abnormalities. The results of experiments with DES in laboratory animals are also reviewed. (123 refs.)

78-2431 **Diet and Nutrition.** (Eng) Newberne, P. M. (Dept. Nutritional Pathology, Massachusetts

Inst. Technology, E18-611, Cambridge, MA, 02139). *Bull NY Acad Med* 54(4): 385-396; 1978.

A review of the association between various dietary and nutritional factors and cancer incidence is presented. Particular attention is focused on the potential role of diet in gastric, colonic, and mammary cancer. (44 refs)

78-2432 **Fiber, Intestinal Sterols, and Colon Cancer.** (Eng) Huang, C. T. (Section Nutrition and Gastroenterology, Dept. Pediatrics, Baylor Coll. Medicine, Houston, TX, 77030); Gopalakrishna, G. S.; Nichols, B. L. *Am J Clin Nutr* 31(3): 516-526; 1978.

The effect of dietary fiber on intestinal function and composition of lipids in the feces and its relationship to colon cancer are considered. Dietary fiber is composed of four major components, cellulose, hemicellulose, lignin, and pectin. Hemicellulose and pectin may increase fecal bile acid excretion in humans, a change that may be accompanied by a decrease in serum cholesterol. Fibers such as rolled oats, alfalfa, guar gum, and Bengal gram have hypocholesterolemic properties. Alfalfa, wheat straw, and some other fibers bound considerable amounts of bile acids in vitro, but wheat bran, oat hulls, and all the synthetic fibers tested bound only negligible amounts. Vegetarians in the US have lower plasma lipids and different plasma lipoprotein patterns than comparable populations on a mixed diet. They also have smaller daily fractional turnover rates of cholic acid and deoxycholic acid pool size. The current dietary fiber intake in the US is approx 20% of what it was a century ago. Diets depleted of fiber may prolong the contact between stool content and mucosa and they may favor the growth of bacterial flora capable of forming carcinogens from the degradation of bile acids. It is suggested that fiber may reduce colon cancer incidence by decreasing intestinal transit time; altering bile acid metabolism and thereby reducing potential carcinogen formation; diluting potential carcinogens as a result of its bulking effect and ability to bind water, sterols, bile acids, and fat; and, through its effect on intestinal flora, by decreasing the bacterial degradation of bile acids and neutral sterols. (90 refs)

78-2433 **Chemical Carcinogens in Plant Food Products (Literature Review).** (Rus) Neiman, I. M. (Inst. Nutrition, Moscow, USSR). *Vopr Pitan* (1): 55-60; 1978.

The carcinogenicity of plant food products is reviewed briefly. The chemical carcinogens contained in these food products can be divided into (1) exogenous carcinogens resulting from contamination due to environmental pollutants, pesticides, or the products of heat treatment and fumigation and (2) endogenous carcinogens synthesized in the plants in vivo. (10 refs)

78-2434 **Mechanism of Action of Mycotoxins.** (Fre) Moule, Y. (Institut de Recherches Scientifiques sur le Cancer, 94800 Villejuif, France). *Ann Nutr Aliment* 31(4/5/6): 803-810; 1977.

Hypotheses concerning the mechanism of the physiological effects induced by mycotoxins, particularly the aflatoxins and the toxin from *Penicillium roqueforti* (PR toxin), are reviewed. Although the long-term effects of the PR toxin are unknown, a lot of data reviewed have accumulated on the hepatocarcinogenic activity of aflatoxin B_1. It is hypothesized that both the carcinogenic and mutagenic effect of aflatoxin B_1 are the result of the mycotoxin's interference with DNA repair. Treatment of cultures of *Escherichia coli* with active metabolites of aflatoxin B_1 derepresses the system of inaccurate DNA repair (SOS system). In bacteria, the SOS system induces the synthesis of repair enzymes that leads to mutagenesis. The carcinogenic effect of aflatoxin could be explained by the tumor produced by successive generations of cells arising from the single cell with a specific mutation. (34 refs)

78-2435 **Mycotoxin Tolerances in Foodstuffs.** (Eng) Krogh, P. (Univ. Inst. Pathological Anatomy, DK-2100 Copenhagen O, Denmark). *Pure Appl Chem* 49(11): 1719-1721; 1977.

Although many mycotoxins produce toxic effects in humans and animals, the only one mentioned specifically in legislation is aflatoxin. Standards for various countries, which are reviewed briefly, cover all foods, those likely to contain the toxin, or trade commodities only. Tolerances for human food range from 0 to 50 ppb; for feeds, the levels are higher. (7 refs.)

78-2436 **Short-Term Tests and Mycotoxins.** (Eng) Malaveille, C. (International Agency Res. Cancer, 150, Cours Albert-Thomas, 69008 Lyon, France); Bartsch, H. *Ann Nutr Aliment* 31(4/5/6): 871-880; 1977.

The value of short-term tests in assessing the possible carcinogenic risk of chemicals and in investigating the mode of biological action of chemicals in mammals and in humans is reviewed, with special attention being focused on results obtained with mycotoxins. Studies have suggested that there is an empirical relationship between carcinogenesis and mutagenesis; this led to the development of many short-term tests for mutagenicity. Bioassays in which malignant transformation is used as the end-point most closely estimate the onset in vivo of neoplastic processes by chemicals; the malignancy of the cell is confirmed by injection of the treated cells into an appropriate host. However, since none of the available tests use the appearance of tumors in mammals as end-points, more than one mutagenicity assay system must be used to ascertain the carcinogenicity and mutagenicity of a chemical. The use of short-term tests with aflatoxins has revealed a good correlation between carcinogenicity and results in rec-assays, mutagenicity assays with *Salmonella typhimurium*, and induction of DNA repair synthesis. For other mycotoxins, such as patulin and luteoskyrin, the data are contradictory. In some instances, short-term tests have allowed determination of the mechanism of action of various carcinogens such as aflatoxin B_1, which forms a covalently bound adduct with hepatic nucleic acids and proteins. (36 refs)

78-2437 **The Effect of Alcohol Consumption on Risk of Cancer of the Head and Neck.** (Eng) Rothman, K. J. (677 Huntington Ave., No. 802, Boston, MA 02115). *In: Head and Neck Cancer. State of the Art Conference, February 16, 17 and 18, 1976.* (St. Louis, MO: Laryngoscope): Vol. 88, No. 1, Part 2, Suppl. 8, pp. 51-55; 1978.

Alcoholics are at increased risk for the development of oral cancers. It is estimated that alcohol plays an etiological role in > 50% of the oropharyngeal cancers in the US. The sites most affected are those that come into direct and prolonged contact with the alcohol, the floor of the mouth and the tongue. The risk from joint exposure to alcohol and tobacco is about 2.5 times the risk expected if the effects of the two substances were additive; a synergistic effect is thus apparent. Although education of the public on the increased risk of oral cancers from alcohol and tobacco use is important, screening programs for at-risk patients would have a more beneficial effect. Research should focus on whether carcinogens in tobacco smoke dissolve in the alcohol and are thus held in more prolonged contact with the oral mucosa or whether certain congeners in the alcohol exert a special effect. (12 refs.)

78-2438 **Assumption of Linearity in Dose-Effect Relationships.** (Eng) Pochin, E. E. (Natl. Radiological Protection Board, Harwell, Didcot, Oxfordshire OX11 OR9, England). *Environ Health Perspect* 22: 103-105; 1978.

Radiation protection standards have developed in three phases. At first, it seemed likely that no harm was caused unless there was a high radiation dose, so that protection from low doses was not considered. It then became clear that even the lowest doses might involve some risk, and the estimate of the possible risk at low dose was made by linear extrapolation from known high dose exposue in human populations developing various types of malignancy. Arguments from microdosimetric and other models have made it increasingly likely that linear and quadratic (ie, dose-squared) terms may determine the dose-effect relationship from low to moderately high dose levels. One of the critical questions is whether the slope of the dose-effect relationship is zero at the dose corresponding to that constantly received from natural sources. A linear hypothesis has also been used to estimate the likely frequency of harm from low doses of chemical substances which have defined harmful effects at high dose. The validity of this procedure depends on the way in which chemical pollutants or their metabolic products become distributed through body tissues and cause the relevant harmful effect on cells. The major difference between the two situations (radiation and chemical carcinogenesis) is the physically predictable nature of the radiation dose to particular tissues or cell structures compared to the less certain knowledge of the distribution and metabolism of chemical pollutants in the body. (12 refs)

78-2439 **Radiation.** (Eng) Upton, A. C. (NCI, Bethesda, MD, 20014). *Bull NY Acad Med* 54(4): 428-434; 1978.

A review of some of the current information on radiation-induced carcinogenesis is presented. It has been suggested that the relation between dose and cancer incidence is linear and that no dose is safe. Extrapolations from dose curves are difficult to assess because of the differing sensitivities of cells to radiation at different doses. The policy question in radiation carcinogenesis is how big is the risk for a given dose. No radiation exposure should be without some benefit, and whatever the exposure, it should be as low as possible. (4 refs)

78-2440 **Irradiated Diets Examined.** (Eng) Cooper, P. (No affiliation given). *Food Cosmet Toxicol* 16(1): 71-73; 1978.

Literature data on the effects of feeding irradiated foods to experimental animals are reviewed. Most of the studies showed no adverse effects of irradiated diets, but one showed that irradiated wheat increased the mutagenic index of nourished and malnourished rats and decreased the number of germ cells in the latter. In another study, polypoid cells were noted in children fed irradiated wheat 4 wk after the start of feeding; none were noted in children fed unirradiated grain. Irradiation has been shown to both increase and have no effect on aflatoxin production. (no refs)

78-2441 **Hiroshima at Home.** (Eng) Commoner, B. (Center Biology Natural Systems, Washington Univ., St. Louis, MO). *Hosp Pract* 13(4): 58, 63; 1978.

A preliminary study of the records of servicemen exposed to radiation from H-bomb tests in Nevada in 1957 indicates an increased incidence of leukemia in these subjects. Studies of workers connected with the uranium mining industry, nuclear submarines, and nuclear installations have found an increased cancer death rate among those exposed to radiation. (no refs)

78-2442 **Virus-associated Malignant Diseases in Animals and Man.** (Eng) Jose, D. G. (Peter MacCallum Clinic, 481 Lt. Lonsdale St., Melbourne, Victoria 3000, Australia). *Aust NZ J Med* 8(2): 195-214; 1978.

Current knowledge of the oncogenicity of DNA and RNA viruses is reviewed. Of the DNA viruses, herpes simplex virus type 2 has been implicated in cervical carcinoma and Epstein-Barr virus in Burkitt's lymphoma and nasopharyngeal carcinoma. Of the RNA viruses, the C-type viruses are associated with leukemias and sarcomas in many species. Molecular hybridization experiments suggest that animal RNA viruses are transmitted horizontally among humans. (253 refs)

78-2443 **Virus and Human Carcinogenesis.** (Ger) Birkmayer, G. D. (Institut fur Zellbiologie, Universitat Munchen, Goethestrasse 33, D-8000 Munich 2, W. Germany). *Wien Med Wochenschr* 127(23): 703-706; 1977.

Although there is no definitive evidence of a viral etiology of human tumors, oncogenic viruses have been isolated from certain human tumors and virus production has been observed in human leukemia cells. In addition, viral reverse transcriptase was found in human leukemia, lymphoma, osteosarcoma, melanoma, glioma, and breast carcinoma. (8 refs.)

78-2444 **Experimental Models and Conceptual Approaches to Studies of Lymphomas and Leukemia: Etiology, Biology, and Control.** (Eng) Ihle, J. N. (Basic Res. Program, NCI Frederick Cancer Res. Center, P.O. Box B, Frederick, MD, 21501). *Semin Hematol* 15(2): 95-115; 1978.

A review of the leukemias and lymphomas of thymus-derived lymphocytes is presented with emphasis on the murine lymphomas. The various topics include viruses and leukemia, spontaneous and environmentally induced leukemias, and leukemias as diseases of differentiation. It is suggested that leukemias with both viral and nonviral etiologies exist and that the former may be amenable to classical immunologic control. (116 refs)

78-2445 **Symposium on Liver Carcinoma. Hepatocellular Carcinoma and Hepatitis B.** (Eng) Zuckerman, A. J. (London Sch. Hygiene and Tropical Medicine, London WC1E 7HT, England). *Trans R Soc Trop Med Hyg* 71(6): 459-461; 1977.

Progress in establishing the progression of hepatitis B to hepatocellular carcinoma is reported. Although the viral surface and core antigens have not been detected in tumor cells, the surface antigen, subtype *ad*, was present in supernatant fluids from the cultured tumor cells of a patient with primary liver cancer, and circulating surface antigen was found in his blood. Liver DNA and RNA from patients with persistent hepatitis B infection and hepatocellular carcinoma significantly accelerated the reassociation rate of radioactive DNA from the 42-nanometer virus particles containing the core antigen. The viral DNA base sequences were alkali-stable, which suggested their attachment to host chromosomes. (13 refs.)

78-2446 **Assembly of Type C Oncornaviruses: A Model.** (Eng) Bolognesi, D. P. (Dept. Surgery, Duke Univ. Medical Center, Durham, NC, 27710); Montelaro, R. C.; Frank, H.; Schafer, W. *Science* 199(4325): 183-186; 1978.

Based on their fine structure, the molecular arrangement of the virion structural components in the particle, and data on the biosynthesis of these components, a model for the assembly of avian and murine C-type oncornavirus is proposed. The model includes the following events. Complexes consisting of the virus envelope components migrate from their sites of synthesis in the cytoplasm to the cell surface and are inserted in the membrane at the site of virus budding. Uncleaved precursor molecules to the internal virus polypeptides are then transported to the budding site, where one end of the precursor molecule is joined to the virus envelope complex and the other end associates with the virus RNA. As viral maturation progresses, proteolytic enzymes cleave the precursor molecules at the appropriate sites, generating the individual structural elements of the virus. The resultant virion components than associate with themselves and/or with other molecules to form the substructures found in the mature virus. The recently established precursor-product relationship between mouse mammary tumor virus A-type particles and mature B-type particles suggests that this class of oncornaviruses may assemble by mechanisms similar to those proposed for C-type particles. (37 refs)

78-2447 **Inhibition of Chemical Carcinogens.** (Eng) Wattenberg, L. W. (Dept. Lab. Medicine and Pathology, Univ. Minnesota, MN); Lam, L. K.; Borchert, P. *In: Carcinogens: Identification and Mechanisms of Action. Proceedings of the Thirty-First Annual Symposium on Fundamental Cancer Research Held at Houston, Texas, 1-3 March 1978.* University of Texas System Cancer Center, M. D. Anderson Hospital and Tumor Institute, NCI, American Cancer Society. (Austin, Texas). 19 pp.; 1978. (no refs)

78-2448 **Erythropoietin and the Control of Red Cell Production.** (Eng) Graber, S. E. (Dept. Medicine, Veterans Admin. Hosp., Nashville, TN, 37203); Krantz, S. B. *Annu Rev Med* 29: 51-66; 1978.

A review of current knowledge on erythropoietin (Ep) is presented. Studies of Ep in cancer patients have indicated that despite the presence of anemia in many patients, there is no increase in Ep levels. The discovery of Ep has also led to a better classification of polycythemia. Polycythemia vera appears to be a clonal disease in which a cell gives rise to erythroid cells in the presence of small amounts of Ep and in which a normal cell line under Ep control is repressed. (109 refs)

78-2449 **The Respiratory Tract and the Environment.** (Eng) Brain, J. D. (Dept. Physiology, Harvard Sch. Public Health, Boston, MA, 02115). *Environ Health Perspect* 20: 113-126; 1977.

The respiratory tract is the most common route of entry of toxic or infectious particles in the working or general environment. Various diseases resulting from inhaled substances and respiratory mechanisms that act to prevent damage are outlined. Neoplastic responses have been observed following inhalation of cigarette smoke, asbestos, polycyclic aromatic hydrocarbons, radioisotopes, chromates, and compounds involved in nickel refining. (32 refs)

78-2450 **Peculiarities in the Occurrence of Adrenal Cortical Carcinoma.** (Eng) Miller, R. W. (Clinical Epidemiology Branch, NCI, A-521 Landow Building, Bethesda, MD, 20014). *Am J Dis Child* 132(3): 235-236; 1978.

A review of patients who developed adrenal cortical carcinoma indicated a substantial incidence of second primary neoplasms, especially those in the brain. The dissimilar neoplasms that occur in family cancer syndromes also develop excessively in these patients as second primary tumors, suggesting a genetic influence. The carcinoma also occurs in patients with congenital hemihypertrophy; and there may be an association between this tumor and others that tend to occur in patients with hemihypertrophy. (15 refs)

78-2451 **Retrospective Analysis of Control Animal Data--The Rat.** (Eng) Haley, T. J. (Natl. Center Toxicological Res., U.S. Dept. Health, Education, and Welfare, Food and Drug Admin., Jefferson, AR, 72079). *Clin Toxicol* 12(2): 249-263; 1978.

Retrospective data are presented on the type, incidence, and latency period of spontaneous tumors in different rat strains. The data are intended as a guide to the selection of control strains in projected studies of carcinogenesis and chronic toxicology. The effect that aging control animals can have on the statistical analysis of experimental data is noted, together with the possible role of virus activation in the development of malignant tumors. (71 refs)

78-2452 **The Role of Epidemiology and Geographic Pathology in Environmental Carcinogenesis.** (Eng) Higginson, J. (International Agency Res. Cancer, Lyon, France). *Bull Am Coll Surg* 63(4): 14-19; 1978.

Although studies have indicated that 70%-90% of all human cancers are related to environmental factors, these factors cover such a wide range (industrial, personal, viral, and general environmental exposure) that total prevention is currently unrealistic. The association of environmental factors with cancer of the esophagus, liver, colon, and rectum is outlined, and the role of physicians in identifying risk factors is reviewed. (13 refs)

78-2453 **Cancer Statistics, 1978.** (Eng) Silverberg, E. (Dept. Epidemiology and Statistics, American Cancer Society, New York, NY) *CA* 28(1): 17-32; 1978.

Figures and tables of estimates of cancer incidence and mortality, based on newly available comprehensive data from the National Cancer Institute's Third National Cancer Survey, are presented. Data are given for all sites and for each major site, but they do not cover carcinoma in situ of the cervix and nonmelanoma skin cancer. According to 1978 estimates of cancer incidence, lung (22%), prostate (16%), and colon and rectum (14%) will be the most common sites in men, breast (26%), colon and rectum (15%), and uterus (33%), in women. Three of the major sites of cancer deaths will be lung (33%), colon and rectum (12%), and prostate (10%) in men, and breast (19%), colon and rectum (15%), and lung (12%) in women. In 1975, cancer was the second leading cause of death (after heart disease) in men and women of all ages (199,443 and 166,250 deaths, respectively). During 1969-1971, the av annual incidence rate (per 100,000) of cancer in children < 15 yr old was 12.5% for all sites, highest for leukemia (4.2), brain and CNS (2.6), lymphoma (1.3), and kidney (0.8). In 1978, the estimated number of new cancer cases in men and women, respectively, will be 352,000 and 348,000 for all sites, 89,400 and 83,200 in the digestive organs, 88,900 and 25,000 in the respiratory system, and 61,800 and 69,200 in the genital organs. The respective highest number of deaths in 1978 will be due to cancer of the digestive organs (55,500 and 50,000), respiratory system (74,300 and 22,850), and genital organs (21,600 and 22,500), with all sites totaling 213,500 and 176,500. Among the remaining statistics are estimated new cancer cases and deaths by state (1978), age-adjusted cancer death rates for 44 countries (1972-1973), and 5-yr survival rates for major sites by stage and sex (1965-1969). (no refs)

78-2454 **Genesis and Spread of Intraepithelial Cervical Neoplasia.** (Ger) Bajardi, F. (Zytologisches Laboratorium, Landeskrankenhaus Graz, Auenbruggerplatz 26, A-8036 Graz, Austria). *Gynaekol Rundsch* 17(1): 7-13; 1977.

Carcinoma in situ and early invasive carcinoma of the uterine cervix are practically always accompanied by epithelial dysplasia. The time required for the dysplasia to progress to carcinoma in situ is estimated at 2-3 yr, and 10-12 yr are required for carcinoma in situ to progress to invasive carcinoma. Intraepithelial neoplasia is the result of transformation of epithelium into another type of epithelium via regeneration (indirect metaplasia). The spread of malignant epithelium is inhibited. Therefore, carcinoma in situ is never able to invade the entire endocervix or ectocervix, in spite of the long latent period involved (10-12 yr). (22 refs)

78-2455 **Eighty Percent of Cancer Is Related to the Environment.** (Eng) Schneiderman, M. A. (NCI, Landow Bldg., Room C403, Bethesda, MD, 20014). *Laryngoscope* 88(4): 559-574; 1978.

A review of epidemiologic data on cancer incidence suggests that as much as 80% of all cancers are related to environmental factors. These factors include personal variables such as cigarette smoking, alcohol consumption, sexual habits, and diet and impersonal variables such as industrial and occupational pollutants, water and air contaminants, pesticides, flame retardants, diet additives, and drugs. Elimination or reduction of these environmental factors would bring about a significant decline in cancer mortality. (18 refs)

78-2456 **An Epidemiologic and Clinical Study of Nasopharyngeal Carcinoma.** (Eng) Ho, J. H. (Medical and Health Dept., Inst. Radiology and Oncology, Queen Elizabeth Hosp., Kowloon, Hong Kong). *Int J Radiat Oncol Biol Phys* 4(3/4): 183-198; 1978.

An etiologic hypothesis for nasopharyngeal carcinoma is postulated from current epidemiologic and experimental data. The three factors thought to be involved are Epstein-Barr virus, a genetically determined susceptibility, and an environmental factor that may vary from one population group to another. In the case of the southern Chinese, especially the boat people living along the south China coast, who have the highest cancer risk, the most probable environmental factor is salted fish in the diet coupled with vitamin C deficiency in early life. When added to the diet of WA albino rats, salted fish induced nasal and paranasal carcinomas. Clinical studies showed a good correlation between prognosis and a grouped Tumor Node Metastases (TNM) stage classification. When patients were matched according to the system, no significant difference in radiotherapy results was observed for the two sexes. As a group, Stage I or II patients, but not Stage III patients, <40 yr old had significantly better 5-yr survival rates than patients aged 40 or over. Prophylactic cervical node irradiation did not improve the survival or tumor control prospects of Stage I patients. Therefore, irradiation of the neck should be withheld until nodal metastases become clinically evident. (44 refs)

78-2457 **Genetic Risk Factors for Malignant Tumors in Humans.** (Ger) Rudiger, H. W. (I. Medizinische Universitatsklinik, Martinistrasse 52, 2000 Hamburg 20, W. Germany). *Dtsch Med Wochenschr* 103(2): 77-84; 1978.

Studies of hereditary malignant tumors, precanceroses, and hereditary diseases associated with increased cancer risk are reviewed. Retinoblastoma, Wilms' tumor, neuroblastoma, pheochromocytoma, malignant melanoma, and Sipple's syndrome can be either hereditary or sporadic. (103 refs)

78-2458 **Asbestos Fiber Dust, an Actual Hazard.** (Ger) Weicksel, P. (Facharzt fur Lungen und Bronchial Heilkunde, Kaiserstrasse 26, D-8700 Wurzburg, W. Germany). *Med Klin* 73(10): 351-356; 1978.

Studies of the hazards of inhaled fine asbestos fibers are reviewed. The carcinogenic effect of asbestos fibers is related to their diameter, length, density, and elasticity, and not to their chemical composition or molecular structure. Two-thirds of all pleural mesotheliomas are believed to be due to industrial noxae such as asbestos. An abnormally high incidence of pleural plaques was found in people living near an asbestos mine in Finland; they were never exposed to asbestos occupationally. Asbestosis was diagnosed roentgenologically in an asbestos weaver 5 yr after he retired, and pleural mesothelioma was detected at autopsy. Asbestosis was found in a bricklayer who had been working with asbestos-containing refractory materials for 30 yr. Investigation of 304 patients with chronic bronchitis (198 smokers, 106 nonsmokers), 88 of whom were exposed occupationally to dusts (including asbestos), revealed that both cigarette smoke and asbestos dust enhance obstructive reactions in the bronchial system or are a possible cause of these reactions. Smoking and asbestos dust had only a moderate additive effect. (20 refs)

78-2459 **Epidemiology of Breast Cancer.** (Ger) Maass, H. (Gyn.-geb. Abt. II der Frauenklinik, Zentralkrankenhaus, Kliniken der Freien Hansestadt Bremen, St.-Jurgen-Strasse, 2800 Bremen, W. Germany). *Roentgenblaetter* 31(7): 401-404; 1978.

Epidemiologic data show that breast cancer in women is 8 to 10 times more frequent in Western industrial countries than in the Far East and in some developing countries. In all groups, late primiparas are at increased risk. Other risk factors are a family history of breast carcinoma, nulliparity, proliferating mastopathy, and a prior breast tumor. (no refs)

78-2460 **Benign and Malignant Liver Neoplasms. Some New Etiologic Associations.** (Eng) Rudolph, R. H. (Mason Clinic, P.O. Box 900, Seattle, WA, 98111). *Postgrad Med* 63(3): 56-60, 62, 65; 1978.

Recent studies of benign and malignant hepatic neoplasms have suggested associations between these tumors and oral contraceptives, androgens, hepatitis virus, and vinyl chloride. It is suggested that hepatic arteriography is the best method for diagnosing hepatic adenomas in women using oral contraceptives. (20 refs)

78-2461 **Environmental Aspects of Injury and Disease: Liver and Bile Ducts.** (Eng) Reynolds, E. S. (Dept. Pathology, Univ. Texas Medical Branch, Galveston, TX, 77550). *Environ Health Perspect* 20: 1-13; 1977.

Mechanisms by which environmental agents interact with the liver and cause liver and biliary damage are surveyed. Known hepatotoxins (vinyl chloride, CCl_4), potential hepatotoxins, cohepatotoxins, mixed-function-oxidase inducers, and potential hepatotoxins that could be encountered in various environments are listed. (27 refs)

78-2462 **Epidemiological Studies of Oral Cancer.** (Eng) Pindborg, J. J. (Dept. Oral Pathology, Royal Dental Coll., Copenhagen, Denmark). *Int Dent J* 27(2): 172-178; 1977.

A review of epidemiologic data indicates that oral cancer is characterized by marked geographic differences. In Norway, lip cancer is 20 times more frequent among men than women, and its occurs with a double frequency in rural areas compared with cities. Cancer of the tongue occurs with the same frequency in men and women. Oral cancer incidence rates increase sharply with age, especially for men. In a series of seven Western countries, Canada has the highest incidence of cancer of the lip, but within Canada there are marked differences. Regional differences in lip cancer incidence within Czechoslovakia have been explained by more UV radiation, more spicy food, and pipe-smoking with a short-stemmed pipe. There is a high relative frequency of oral cancer in most countries of Southeast Asia. In Singapore, both male and female Indians and Pakistanis have much higher incidence rates than the other ethnic groups (Chinese, Malays, Europeans). This difference is likely due to the chewing of tobacco together with betel nut and also the occurrence of oral submucous fibrosis. Most of the studies dealing with the etiology of oral cancer have implicated tobacco usage. (16 refs)

78-2463 **The Interactions of Smoking, Environment and Heredity and Their Implications for Disease Etiology. A Report of Epidemiological Studies on the Swedish Twin Registries.** (Eng) Cederlof, R. (Dept. Environmental Hygiene, Karolinska Inst., Stockholm, Sweden); Friberg, L.; Lundman, T. *Acta Med Scand [Suppl]* 612: 105-128; 1977.

Using data compiled by the Swedish Twin Registries, the interactions of smoking, environment, and heredity on disease etiology were reviewed. Morbidity studies revealed associations between smoking and lung cancer and other respiratory diseases. (159 refs)

78-2464 **Re: Smoking and Cancer of the Uterine Cervix: Hypothesis (Letter to Editor).** (Eng) Schoenberg, B. S. (Section on Epidemiology, Natl. Inst. Neurological and Communicative Disorders and Stroke, Bethesda, MD, 20014). *Am J Epidemiol* 107(4): 353-354; 1978.

In a previous study, a high correlation was found between the age-adjusted incidence rates for cancers of the uterine cervix and lung, and a relationship between smoking and cervical cancer was suggested. Literature dealing with multiple primary cancers that also support this association are cited. Each of the cancer cites linked to cervical cancer was strongly correlated with cigarette smoking. Heavy cigarette consumption may be associated with the subgroups of women at high risk of cervical cancer or it may play a more direct role in the etiology of this cancer. (10 refs)

78-2465 **Characterization of Polycyclic Aromatic Hydrocarbons in Sewage Sludge by Gas Chromatography.** (Ger) Grimmer, G. (Biochemisches Institut fur Umweltcarcinogene, Sieker Landstrasse 19, D-2070 Ahrensburg, W. Germany); Bohnke, H.; Borwitzky, H. *Fresenius Z Anal Chem* 289(2): 91-95; 1978.

Eighteen polycyclic aromatic hydrocarbons were determined in sewage sludge samples by gas chromatography combined with mass spectrometry. They included fluoranthene, pyrene, benzo(a)fluorene, benzo(b/c)fluorene, benz(a)anthracene, chrysene, benzo(a)pyrene, perylene, dibenz(a,j)anthracene, and anthanthrene. (6 refs)

78-2466 **Absolute Stereochemistry of *cis*-1,2-, *trans*-1,2-, and *cis*-3,4-Dihydrodiol Metabolites of Phenanthrene.** (Eng) Koreeda, M. (Dept. Chemistry, Johns Hopkins Univ., Baltimore, MD, 21218); Akhtar, M. N.; Boyd, D. R.; Neill, J. D.; Gibson, D. T.; Jerina, D. M. *J Org Chem* 43(6): 1023-1027; 1978.

The absolute stereochemistry of the *cis*-1,2-, *cis*-3,4-, and *trans*-1,2-dihydrodiols of phenanthrene was determined by the exciton chirality circular dichroism method and chemical degradation. The results represent the first determination of the absolute stereochemistry of a bay region dihydrodiol; ie, *cis*-3-hydroxy-4-benzoyloxy-1,2,3,4-tetrahydrophenanthrene. (78 refs)

78-2467 **Glutaminase and Glutamine Synthetase in 20-Methylcholanthrene Treated Mice.** (Eng) Bhattacharya, M. (Indian Inst. Experimental Medicine, Calcutta 700032, India); Maity, P.; Chaudhuri, L.; Banerjee, S.; Shrivastava, G. C. *Indian J Exp Biol* 15(1): 52-53; 1977.

Levels of glutamine synthetase (GS) and glutaminase were studied in the liver and skin of male Swiss mice treated with 20-methylcholanthrene. A single brush stroke of the carcinogen (0.5% in benzene) was applied thrice weekly for an av of 14 wk to the shaved dorsal skin. After the initiation of treatment, hepatic GS activity increased up to 30 days and then slowly decreased with the appearance of hyperplasia. It regained normal levels by 90 days. In animals treated with benzene only, GS activity remained constant after an initial 30-day increase. Glutaminase activity in the skin increased for 90 days, but the activity in benzene-treated animals returned to normal after peaking at 45 days. Glutaminase activity in the liver also increased with tumor progression. It appears that the initial rise in GS activity meets the requirement of glutamine for tumor growth; the remaining enzyme activity was adequate to maintain normal plasma glutamine levels. The rises in glutaminase activity confirm an increased demand for glutamine by the tumor-host system. (16 refs)

78-2468 **Fractionation of 3M KCl Extracts from the Methylcholanthrene Induced Fibrosarcoma, MCA-F (Meeting Abstract).** (Eng) Pellis, N. R. (Univ. Texas Health Science Center, Houston, TX, 77030); Yamagishi, H.; Wiseman, F. C.; LeGrue, S.; Kahan, B. D. *Fed Proc* 37(6): 1562; 1978. (no refs)

78-2469 **Studies on the Specificity of In Vitro-induced Lymphocytotoxicity to Methylcholanthrene-induced Fibrosarcoma Cell Lines.** (Eng) Warnatz, H. (Inst. Policlinic Clinical Immunology, Univ. Erlangen, Univ. Erlangen, D 8520 Erlangen, W. Germany); Koops, A. C.; Meissner, K.; Hiemeyer, K. *Cell Immunol* 35(2): 436-447; 1978.

To study the specificity of cytotoxic reactions to methylcholanthrene-induced fibrosarcoma (MCAF) cells, cytotoxic effector lymphocytes were induced by in vitro immunization of lymph node and spleen cells from C57B16(H2b) and BALB/c(H2d) mice to syngeneic and allogeneic MCAF cell lines. The T-cell-dependent cytotoxicity was specific to target cell lines to which the lymphocytes were immunized in vitro. Lymphocytotoxicity to syngeneic MCAF cells or normal syngeneic fibroblasts could not be induced using normal fibroblasts as stimulators. With allogeneic MCAF cells, cytotoxic reactions to alloantigens, but not to tumor-associated antigens, were detected. Phytohemagglutinin (10 μg/6 x 10^7 lymphocytes) induced a nonspecific cytotoxic effect that increased the specific lysis of target cells: allogeneic and syngeneic target cells were destroyed by the effector cells. The cytotoxicity of the in vitro-immunized lymphocytes was inhibited by incubation with membrane protein preparations from syngeneic MCAF cell lines. However, the membrane extract of one individual syngeneic cell line inhibited the lymphocytotoxicity to all other syngeneic cell lines. Membrane protein preparations from allogeneic MCAF cells or from normal syngeneic fibroblasts were not inhibitory. In vitro-immunized cytotoxic lymphocytes did not impair the in vivo tumor growth. (22 refs)

78-2470 **Solubilization and Partial Characterization of Tumour-specific Transplantation Antigens from**

hemically-induced Sarcomas. (Meeting Abstract). (Eng) ikora, K. (Lab. Molecular Biology, Hills Road, Cambridge, ngland); Koch, G.; Lennox, E. *Br J Cancer* 37(3): 472; 1978. no refs)

8-2471 **Methyl Cholanthrene and Cadmium Induced Changes in Rat Prostate.** (Eng) Scott, R. (Dept. rology, Royal Infirmary, Glasgow, Scotland); Aughey, E. *r J Urol* 50(1): 25-28; 1978.

he effects of cadmium and 20-methylcholanthrene (20-MC) n the prostate gland of Wistar rats were compared. There ere three treatment groups: Group 1 (53 rats) received 0-MC directly in the ventral and dorsolateral lobes of the rostate; Group 2 (207 rats) received 0.05 ml of a 1 M soln nd 0.1 ml of a 1 M soln of $CdCl_2$ directly into the ventral nd dorsolateral lobes of the prostate; Group 3 (50 rats) was ubdivided into five groups that received five incremented oses of 0.05 ml of a 1 M soln $CdCl_2$ soln sc. Tumors were resent in 19 Group 1 animals; stratification was noted in 11 nd hyperplasia in 7. In Group 2, 17 tumors, 52 cases of astrate regression, and 80 cases of stratification were detectd. In Group 3, only 1 early tumor was noted; however, 15 ases of castrate regression, 5 of stratification, and 1 tumor n another organ were found. The most common types of umor found in Group 2 animals were tumors of the supportng tissue; the appearance of clear cells and an increase in the umber of cells in the lining of the acini were also noted. Most f the Group 1 tumors were fibrosarcomas and squamous cell arcinomas. The role of Cd in carcinogenesis and its interacion with Zn, which occurs in high concentrations in several issues, including the prostate, is complicated. Zn can obviate ome of the effects of Cd in experimental animals and it can iminish the likelihood of development of testicular tumors. 15 refs)

8-2472 **Immunochemical Evidence of a Tumor-specific Surface Antigen Obtained by Detergent Soluilization of the Membranes of a Chemically Induced Saroma, Meth-A.** (Eng) Natori, T. (Dept. Pathology, Hokkaido niv. Sch. Medicine, Sapporo, 060, Japan); Law, L. W.; Apella, E. *Cancer Res* 38(2): 359-364; 1978.

he immunochemical characterization of a tumor-specific urface antigen (TSSA), which was first found in the final roduct of partially purified detergent-solubilized pecific tumor rejection antigen (TSTA) of a chemially induced sarcoma, Meth-A, is reported. TSSA as isolated by binding to an in vivo-absorbed rabbit nti-TSSA antiserum and was solubilized by detergent, onidet P40. It was further purified through gel iltration, isotachophoresis, and polyacrylamide gel lectrophoresis. The most highly purified TSSA obtained hrough these procedures retained some TSTA activity, suggesting an association between the two antigenic activities. However, the specific activities of both TSSA and TSTA do not suggest copurification. The values obtained show a specific 50-fold increase for TSSA and less than a 1.2-fold increase for TSTA which appears to suggest the existence of two different molecules. Both antigens have a mol wt of 60,000 and an electrophoretic mobility of α-globulin. (18 refs.)

78-2473 **Carcinogen-Protein Complexes in Hamster Colon and Glandular Stomach During Long-Term Administration of 3-Methylcholanthrene.** (Eng) Brodsky, L. H. (Inst. Cancer Res., Fox Chase Cancer Center, 7701 Burholme Ave., Fox Chase, Philadelphia, PA, 19111); Feinberg, R. F.; Sorof, S. *Cancer Res* 38(6): 1654-1660; 1978.

The types and amounts of carcinogen-protein complexes present in the colon and glandular stomach cytosols of male Syrian BIO 87.20 hamsters following long-term administration of 3-methylcholanthrene (3-MC) were investigated. The hamsters were gastrically intubated with 4.0 mg 3-MC three times a week for 0, 1, 3, 6, or 9 wk. On the third day after the final intragastric dose, each hamster received a single ip injection of 100 μCi ^{3}H-3-MC; 24 hr later, the cytosols were prepared and their constituents resolved according to molecular size by Sephadex G-200 gel chromatography. The carcinogen-protein complexes of the colon and glandular stomach cytosols were of similar and unchanging molecular size distributions during the 9 wk of 3-MC administration. The main carcinogen-protein complexes in both organ cytosols had mol wts of 80,000-90,000 daltons. The formation of these complexes apparently required metabolism of the carcinogen, since only small amounts were generated in vitro by incubation of the carcinogen with the organ cytosols at 1-4 C. More than 97% of the complexes in this size class were from the two organs per se and not from the blood they contained. (20 refs)

78-2474 **Anti-Carcinogenic Properties of Vitamin A and its Structural Analogues Studied in Organ Culture (Meeting Abstract).** (Eng) Lasnitzki, I. (Strangeways Res. Lab., Cambridge, England). *Br J Cancer* 37(3): 475; 1978. (no refs)

78-2475 **Biological Activity and Metabolism of the Retinoid Axerophthene (Vitamin A Hydrocarbon).** (Eng) Newton, D. L. (NCI, Bethesda, MD, 20014); Frolik, C. A.; Roberts, A. B.; Smith, J. M.; Sporn, M. B.; Nurrenbach, A.; Paust, J. *Cancer Res* 38(6): 1734-1738; 1978.

The biological activity of axerophthene, a hydrocarbon analog of retinol that may inhibit mammary carcinogenesis, was investigated both in vitro and in vivo. In tracheal organ culture, axerophthene reversed the keratinization caused by a deficiency of retinoid in the culture medium; its potency was of the same order of magnitude as that of retinyl acetate. The analog also supported growth in Syrian golden hamsters fed a vitamin A-deficient diet, but it was less efficient than retinyl acetate. Axerophthene was considerably less toxic than retinyl acetate when administered repeatedly in high doses to rats. Administration of an equivalent po dose of axerophthene caused much less deposition of retinyl palmitate in the liver than did the same dose of retinyl acetate. However, a greater level of total retinoid was found in the mammary gland after administration of axerophthene. The biological activity of axerophthene in tracheal organ culture suggests that enzymatic mechanisms for the activation of retinoids are not confined to the liver and that nonhepatic tissues may play an important role in the metabolism of retinoids. (20 refs)

78-2476 **Spectroscopic Studies of Carcinogen-DNA Complexes. Structure of the Covalent Benzo(a)pyrene 7,8-Dihydrodiol 9,10-Oxide-DNA Adduct (Meeting Abstract).** (Eng) Geacintov, N. E. (Chemistry Dept., New York Univ., New York, NY, 10003); Prusik, T. *Proc Am Assoc Cancer Res* 19: 88; 1978. (no refs)

78-2477 **The Reaction of Trans-7,8-Dihydroxy-Anti-9,10-Epoxy -7,8,9,10- Tetrahydrobenzo(a)pyrene with DNA Involves Attack at the N^7-Position of Guanine Moieties.** (Eng) Osborne, M. R. (Chemical Carcinogenesis Div., Institute Cancer Res., Chalfont St. Giles, Bucks HP8 4SP, England); Harvey, R. G.; Brookes, P. *Chem Biol Interact* 20(1): 123-130; 1978.

The reaction of trans-7,8-dihydroxy-anti-9,10-epoxy-7,8,9,10-tetrahydrobenzo(a)pyrene (anti-BPDE) with DNA labeled with ^{14}C- and ^{3}H-purine precursors indicated that in addition to the previously reported N^2-position of guanine, the reaction also involves the N^7-position of guanine. The hydrocarbon-N^7-guanine product was not detected earlier because it is lost from the DNA very readily at pH 7. The same N^7-product was obtained by the reaction of anti-BPDE with guanine in dimethylformamide. (24 refs)

78-2478 **Identification of the Major Adducts Formed by Reaction of Benzo(a)pyrene Diol Epoxide with DNA in Vitro.** (Eng) Straub, K. M. (Lab. Chemical Biodynamics, Univ. California, Berkeley, CA 94720); Meehan, T.; Burlingame, A. L.; Calvin, M. *Proc Natl Acad Sci USA* 74(12): 5285-5289; 1977.

Covalent binding of the benzo(a)pyrene (BP) metabolite (±)7β,8α-dihydroxy -9α,10α- epoxy -7,8,9,10-tetrahydro benzo(a)pyrene to calf thymus DNA was investigated in a microsome-mediated reaction system. Enzymatic hydrolysis of the carcinogen-modified DNA and subsequent separation of the products via reversed-phase high-pressure liquid chromatography resulted in the detection and isolation of seven distinct compounds. High-resolution mass spectrometry indicated that these products are covalent adducts of deoxyguanosine, deoxyadenosine, and deoxycytidine. The deoxyguanosine and deoxyadenosine adducts involve binding between the activated hydrocarbon (BP diol epoxide) and exocyclic amino groups of the respective pyrines, but the deoxycytidine adduct may involve O^2, N-3, or N^4 alkylation. These results provide an unambiguous determination of the overall molecular structures of the products obtained in the alkylation of DNA by BP diol epoxide, but the effects of these modifications on DNA structure or how they might alter the functional properties of nucleic acids in vivo remain unknown. 78-2482 **Effect of NO$_2$ and SO$_2$ Inhalation on Benzo(a)pyrene Metabolism in Rat Lung.** (Eng) Husain, M. M. (Industrial Toxicology Res. Centre, P.O. Box 80, Lucknow, India); Dehnen, W. *Arch Toxicol (Berl)* 40(3): 207-210; 1978.

Male Wistar rats were continuously exposed to NO_2 (14.4 ppm) and/or SO_2 (46.5 ppm), and the effect of these gases on lung microsomal aryl hydrocarbon [benzo(a)pyrene(BP)] hydroxylase (AHH) activity was determined. Prior to exposure animals were administered methylcholanthrene (MC) to investigate the effect of the exposure on enzyme inducibility and pattern of BP metabolites. NO_2 significantly increased AHH activity, but no marked change was noted with SO_2. Induction of AHH by MC was inhibited markedly by SO_2, only slightly by $NO_2 + SO_2$, but not at all by NO_2. (15 refs)

78-2483 **Aryl Hydrocarbon Hydroxylase in an Insect, *Spodoptera eridania* (Cramer).** (Eng) Anderson, R. S. (Donald S. Walker Lab., Sloan-Kettering Inst. Cancer Res., 145 Boston Post Road, Rye, NY, 10580). *Comp Biochem Physiol [C]* 59(1): 87-93; 1978.

The ability of the armyworm (*Spodoptera eridania*) to metabolize benzo(a)pyrene (BP) was determined. Aryl hydrocarbon hydroxylase (AHH) activity was measured by a highly sensitive radioisotopic method. *S. eridania* larvae metabolized BP via a microsomal mixed-function oxidase system. AHH activity required the presence of NADPH and O_2 in the medium, but it was inhibited by CO, indicating cytochrome involvement. Optimal reaction conditions were a temperature of 30 C and a pH of 7.6-8.0. Measurable BP products were observed within 2 min following initiation of the reaction. The reaction was linear for 20 min, after which it rapidly leveled off; however, BP metabolism continued throughout the 60-min experimental period. The midgut, or stomach, appeared to be the only tissue rich in BP hydroxylase. Subcellularly, AHH was found to be located primarily in the microsomal fraction. The levels of AHH activity were low in young larvae; they gradually increased with maturity but then declined during the prepupal stage. The activity of BP hydroxylase in mice (male C57BL/6 and male Camm Swiss-Webster) is six times that in *Spodoptera*. This study shows that microsomal BP-metabolizing enzyme systems can be found in phyla lower than the vertebrates and, therefore, that BP may be potentially carcinogenic for insects. (21 refs)

78-2484 **Biological Properties of an Olefin Sulfate.** (Rus) Pyleva, Z. A. (A. N. Sysin Inst. General and Communal Hygiene, USSR Acad. Medical Sciences, Moscow, USSR); Voronin, V. M.; Sautin, A. I. *Vopr Onkol* 24(1): 55-60; 1978.

To determine whether surface-active compounds can enhance polycyclic aromatic hydrocarbon-induced carcinogenesis in experimental animals, CBA x C57BL/6 mice received a single epicutaneous application of benzo(a)pyrene (BP: 100 μg). The animals were then divided into two groups, and 2 wk after BP application the mice in Group 1 received an application of Progress-1 (a preparation with a 16.5% content of a surface-active compound, an olefin sulfate) and the mice in Group 2, an application of Progress-2 (a preparation with a 24.5% content of olefin sulfate). Progress-1 and Progress-2 alone did not induce skin tumors, but 19.4% of the mice exposed to BP alone developed skin tumors (av latent period was 53.7 wk). Combined exposure to BP and Progress-2, however, significantly enhanced tumorigenesis: 68.7% of the mice developed skin tumors with an av latent period of 40.9 wk. The corresponding figures for mice exposed to BP and Progress-1 were 19.6% and 53.3 wk. (19 refs)

78-2485 **Comparison of Benzo(a)pyrene Metabolite Formation in Liver Microsomes and Cultured Primary Rat Liver Parenchymal Cells (Meeting Abstract).** (Eng) Huisingh, J. L. 78-2487 **Different Tumours Induced by Benzo(a)pyrene and Its 7,8-Dihydrodiol Injected into Adult Mouse Salivary Gland.** (Eng) Wigley, C. B. (Dept. Cellular Pathology, Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2 A3PX, England); Amos, J.; Brookes, P. *Br J Cancer* 37(5): 657-661; 1978.

Tumors induced by the injection of benzo(a)pyrene (BP) or its proposed proximate carcinogen, benzo(a)pyrene 7,8-dihydrodiol (BP 7,8-dihydrodiol), into the submandibular salivary gland of adult C57BL mice were compared. Mice were injected with 0.1, 0.5, or 2.0 mg BP/mouse or 0.1, 0.25, 0.5, or 1.0 mg BP 7,8-dihydrodiol/mouse. The mice were checked regularly for 1 yr for the presence of tumors. BP induced salivary gland tumors at injection site, but BP 7,8-dihydrodiol induced malignant lymphosarcomas at distant sites, particularly the thymus gland. Many of these lymphosarcomas were metastatic to one or more additional sites, such as lung, liver, and kidney, whereas the BP-induced tumors did not metastasize. The highest dose of both compounds induced fewer tumors than the optimal 0.5 mg/mouse. BP was more active than its derivative in this system (90% and 50% tumor incidences, respectively, at 0.5 mg). The different sites of action of the two carcinogens may be due to their different water solubilities and toxicity. (24 refs)

78-2488 **Conformation of Dinucleoside Monophosphates Modified with Benzo[a]pyrene-7,8-dihydrodiol 9,10-Oxide as Measured by Circular Dichroism.** (Eng) Frenkel, K. (Inst. Cancer Res. and Dept. Biochemistry and Medicine, Columbia Univ., Coll. Physicians, New York, NY, 10032); Grunberger, D.; Boublik, M.; Weinstein, I. B. *Biochemistry (Easton)* 17(7): 1278-1282; 1978.

The conformation properties of GpU modified with the reactive derivative of benzo(a)pyrene (BP), (+)-7β,9α-dihydroxy- 9-5a-10α-epoxy- 7,8,9,10-tetrahydrobenzo(a)pyrene (BPDE), were investigated using circular dichroism spectroscopy. Binding of BPDE to the N^2 of guanosine residues in GpU resulted in the formation of four compounds representing two pairs of diastereoisomers. The molar ellipticity values of the modified dimers were two times higher than those of the modified guanosine monomers. These values were decreased appreciably when the spectra of the dimers were obtained at 80 C or in methanol, rather than at 25 C in water, suggesting that under the latter conditions there is a stacking interaction between the carcinogen and the neighboring uridine residue. Based on these results, a conformation is proposed for modified GpU, it includes insertion of the BP moiety, by rotation of the modified guanine residue about its glycoside bond, coplanar to the neighboring uridine and perpendicular to the phosphodiester backbone. Although this is the most likely interpretation, the data do not exclude other mechanisms. Definitive assignments of the conformations of BPDE-modified dimers require further studies. (29 refs)

78-2489 **A Rapid Spectrofluorometric Method for the Analysis of Polycyclic Aromatic Hydrocarbons in Animal Tissues (Meeting Abstract).** (Eng) Mitchell, C. E. (Inhalation Toxicology Res. Inst., P.O. Box 5890, Albuquerque, NM, 87115). *Fed Proc* 37(6): 1710; 1978. (no refs)

78-2490 **Effect of Monooxygenase Inducers on the Binding of Benzo(A)Pyrene Metabolites to Cellular Macromolecules in Perfused Rat Lungs (Meeting Abstract).** (Eng) Klaus, E. (Dept. Pharmacology, Univ. Mainz, Obere Zahlbacher Strasse 67, D-6500 Mainz, W. Germany); Deckers-Schmelzle, B.; Kahl, G. F. *Naunyn Schmiedebergs Arch Pharmacol* 302(Suppl): R23; 1978. (no refs)

78-2491 **Morphology of Experimentally Induced Respiratory Tumors in Syrian Golden Hamster. A Histological, Histochemical and Ultrastructural Study.** (Eng) Stenback, F. (Dept. Pathology, Univ. Oulu, Oulu, Finland). *Acta Otolaryngol Suppl (Stockh)* 347: 1-59; 1977.

Respiratory tumors and their precursors induced by intratracheal (it) instillation of polycyclic hydrocarbons [benzo(a)pyrene, 9,10-dimethylbenz(a)anthracene, 7H-dibenzo(c,g)-carbazole, or dibenz(a,i)pyrene] in Syrian golden hamsters were studied and compared with lung tumors and nonneoplastic lesions in man. The early metaplastic changes in the tracheobronchial epithelium were similar to those in humans, and they included squamous and transitional cell metaplasia, lack of cilia, formation of club-shaped or multibranched cilia, dysplastic alterations, cytological abnormalities, and widened intercellular spaces with villous interdigitations and sparse desmosomes. A significantly increased incidence of metaplastic and hyperplastic changes was observed prior to the manifestation of visible tumors. The most frequent malignant tumors in hamsters were squamous cell carcinomas of varying differentiation. Other induced tumor types included epithelial adenocarcinomas, sarcomas, carcinosarcomas, and combined adenoepidermoid carcinomas. Of the 852 tumors observed, 34% were benign and 66% were malignant. The av latency period was 42 wk, with undifferentiated tumors having a shorter latent period. Concerning location, 37% were located in the trachea, 20% in the main bronchi, 9% in the bronchiolar area, and 34% in the peripheral lung. The results show that instillations of carcinogens induce a large number of tumors of different types that are also found in man. (167 refs)

78-2492 **Benzo[a]pyrene Metabolizing Activity of Cultured Cells as Determined by a Simplified Radiometric Method.** (Eng) Miyazawa, T. (Dept. Experimental Radiology, Aichi Cancer Center Res. Inst., Tashiro-cho, Chikusa-ku, Nagoya 464, Japan); Enaka, K.; Umeda, M. *Gann* 68(6): 737-744; 1977.

Benzo(a)pyrene (BP) metabolism in cultured mammalian cells was measured by a simplified method. Cells growing in the bottom of glass test tubes were treated with 2 μM of ^{14}C-BP for 24 hr; unmetabolized BP was then extracted with organic solvents, and the amount of water-soluble products recovered in the aqueous phase was measured by a liquid scintillation counter. Among rodent embryo cells, embryo cells of C3H/He mice and Syrian hamsters showed greater BP-metabolizing activity than those of DDD, AKR, and C57BL/6 mice. Several cell lines sensitive to density-dependent inhibition (Y-AK, DL1, and C3H/10T1/2) actively metabolized BP to water-soluble products. The metabolizing activity of C3H/He mouse embryo cells was markedly enhanced by pretreating the cells with benz[a]anthracene. The amount of water-soluble BP products from phytohemagglutinin-stimulated human lymphocytes was much less than that from most cultured cell lines and embryo cells, but the amount increased with time in culture. (30 refs)

78-2493 **A Human Plasma Protein that Binds Benzo(a)-Pyrene (Meeting Abstract).** (Eng) Busbee, D. L.

(North Texas State Univ., Denton, TX, 76203); McKenzie, M.; Snodgrass, D.; Wray, N. P.; McLemore, T.; Cantrell, E. T. *Fed Proc* 37(6): 1721; 1978. (no refs)

78-2494 **Tentative Identification of Benzo[a]pyrene Metabolite-Nucleoside Complexes Produced In Vitro by Mouse Liver Microsomes.** (Eng) Pelkonen, O. (Developmental Pharmacology Branch, Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD, 20014); Boobis, A. R.; Yagi, H.; Jerina, D. M.; Nebert, D. W. *Mol Pharmacol* 14(2): 306-322; 1978.

Seven of nine column chromatography peaks that are consistently found during the binding of benzo(a)pyrene (BP) to DNA in vitro have been tentatively identified. ^{3}H-BP was incubated in vitro with deproteinized salmon sperm DNA, NADPH, and mouse liver microsomes. The resulting covalently bound BP metabolite-nucleoside complexes were resolved into nine distinct peaks by elution of a Sephadex LH-20 column with a water-methanol gradient. Using synthetic and biologically produced metabolites, 7/9 peaks were assigned to one or more BP metabolites. Four of the peaks contained products of BP quinones that are further metabolized. One peak reflected almost exclusively both the *cis-* and *trans*-7,8-diol 9,10-epoxides of BP. Another peak represented predominantly the K-region metabolite (4,5-oxide), interacting with one or more nucleosides. The seventh identified peak comprised reactive intermediates resulting from the further metabolism of BP phenols. BP may therefore be metabolized to four different types of reactive intermediates capable of binding to DNA: primary arene oxides, diol epoxides, phenols oxygenated further, and quinones oxygenated further (or quinone-derived free radicals). The last three types of microsomally activated intermediates are the result of two- or three-step enzymatic processes in which cytochrome P-450-mediated monooxygenations occur at least two times. (50 refs)

8-2495 **Investigations on the Carcinogenic Burden by Air Pollution in Man. Intratracheal Instillation Studies with Benzo(a)pyrene in Bovine Serum Albumin in Syrian Hamsters.** (Eng) Ketkar, M. (Abteilung fur Experimentelle Pathologie, Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, 3000 Hannover 61, W. Germany); Reznik, G.; Schneider, P.; Mohr, U. *Cancer Lett* 4(4): 235-239; 1978.

Male and female Syrian golden hamsters were given weekly intratracheal instillations of 0 (Group 1), 0.1 (Group 2), 0.33 (Group 3), or 1.0 mg (Group 4) of benzo(a)pyrene (BP) in 0.2 ml 10% bovine serum albumin for life and examined for the occurrence of tumors. No respiratory tract tumors were noted in Group 1. Of 26 Group 2 males, 5 had lung tumors; of 30 females, 2 had tracheal and 10 had lung tumors. Of 29 Group 3 males, 5 had tracheal and 2 had lung tumors; of 28 females 7 had tracheal and 6 had lung tumors (total of 10 affected females). Of 27 Group 4 males, 5 had tracheal and 2 had lung tumors (6 affected); of 30 females, 3 had tracheal and 6 had lung tumors (6 affected). Survival rates decreased significantly with increasing BP doses. The increased lung tumor incidence was related to longer survival time; tracheal tumor incidence rose with increasing doses. The tracheal neoplasms were all squamous cell papillomas with the exception of a squamous cell carcinoma in Group 2. All lung neoplasms in Group 2 were bronchogenic adenomas; similar tumors occurred in Groups 3 and 4, in addition to one adenocarcinoma in a Group 3 female and squamous cell carcinomas in three Group 4 females. Respiratory tract lesions, ie, metaplastic and dysplastic alterations of the epithelium as well as the occurrence of alveolar macrophages containing brown pigmentation, were more frequent in females than in males. Respiratory tract tumors were also more frequent in females than in males. (9 refs)

78-2496 **Metabolism of Benzo(a)Pyrene by Human Lymphocytes from Donors of Low, Intermediate, and High Aryl Hydrocarbon Hydroxylase Inducibility (Meeting Abstract).** (Eng) Vaught, J. B. (Roswell Park Memorial Inst., Buffalo, NY, 14263); Gurtoo, H. L.; Paigen, B.; Minowada, J.; Sartori, P.; Tabron, D. *Clin Res* 26(3): 595A; 1978. (no refs)

78-2497 **The Relationship Between Transformation and Somatic Mutation in Human and Chinese Hamster Cells.** (Eng) Spandidos, D. A. (Dept. Medical Genetics, Univ. Toronto, Toronto, Ontario, M5S 1A8, Canada); Siminovitch, L. *Cell* 13(4): 651-662; 1978.

The frequencies of benzo(a)pyrene (BP)- and urethane-induced transformation of primary human and Chinese hamster lung fibroblasts were compared with spontaneous and induced frequencies of mutation for resistance to thioguanine and ouabain and for ability to use fructose. The rates and frequencies of mutation were similar in the two cell systems, but transformation to morphologically altered cells was observed only in hamster cells. Optimal concentrations for hamster cell transformation were 1.0×10^{-6} M BP and 1.1×10^{-2} M urethane. The frequency of transformation in these cells was about 10^3 greater than the frequencies of mutation. The chemically transformed hamster cells did not grow in agar (*aga*-) and did not produce tumors when injected into animals. The frequency of transition of these cells to *aga*+ cells, which produce tumors in animals, was similar to the mutationlike events. (41 refs)

78-2498 **Quantitative In Vitro Metabolism of Benzo(a)pyrene (BP) to Intermediates Cytotoxic and Mutagenic to Mammalian Cells (Meeting Abstract).** (Eng) Kouri, R. E. (Dept. 78-2500 **Benzo(a)pyrene Metabolism and Blast Transformation in Peripheral Blood Mononuclear Cells from Smoking and Nonsmoking Populations and Lung Cancer Patients.** (Eng) Jett, J. R. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901); Moses, H. L.; Branum, E. L.; Taylor, W. F.; Fontana, R. S. *Cancer* 41(1): 192-200; 1978.

Benzo(a)pyrene (BP) metabolism and lymphocyte transformation in peripheral blood mononuclear cells were evaluated in three groups of male patients: 50 healthy nonsmokers, 50 smokers ($>$ 1 pack/day, and 50 lung cancer patients, primarily Stage I, evaluated before radiation therapy or chemotherapy. BP metabolism was assayed by quantitation of the water-soluble products produced from ^{3}H-BP over an 8-hr reaction, and lymphocyte transformation was measured by ^{3}H-thymidine incorporation. The mean level of BP metabolism was significantly higher in the smoking control group, but it was not significantly different in the nonsmoking control and the lung cancer groups. Although 38/57 lung cancer patients had Stage I disease, lymphocyte transformation was significantly lower in the patient group compared with the two control groups. Two factors indicated that the degree of lymphocyte transformation by mitogens influences BP metabolism. First, the mean level of BP metabolites in lung cancer patients with lymphocyte stimulation $< 10^4$ cpm was significantly lower than the level in patients with stimulation $> 10^4$ cpm. Secondly, when mononuclear cells from three control patients were stimulated with variable mitogen concentrations, there was a significant correlation between water-soluble metabolite production and the degree of lymphocyte transformation. (33 refs.)

78-2501 **The Effect of Asbestos-associated Metal Ions on the Binding of Benzo(a)pyrene to Macromolecules In Vitro.** (Eng) Thomson, R. (Natl. Res. Inst. Occupational Diseases, South African Medical Res. Council, P.O. Box 4788, Johannesburg 2000, S. Africa); Kilroe-Smith, T. A.; Webster, I. *Environ Res* 15(2): 309-319; 1978.

The effect of asbestos-associated trace metals on the degree of binding of benzo(a)pyrene (BP) to DNA and other cellular macromolecules was tested in vitro using a rat liver microsomal activation system. Most of the metals tested (nickel, cadmium, chromium, zinc, manganese, and copper) decreased the binding of BP in microsomal incubations containing exogenous DNA. That this represented a reduction in the binding to DNA was confirmed in the cases of zinc, nickel, and chromium. Magnesium caused a slight increase in binding, and iron, both ferrous and ferric, while reducing the binding to DNA, increased the binding to some high-mol-wt component in the incubation mixtures over a narrow concentration range. These results provide evidence that trace metals may play some part in the binding of BP to cellular macromolecules and, therefore, in its carcinogenicity. The effect of iron in increasing the binding of BP in vitro may be particularly significant, because both crocidolite and amosite asbestos have high iron contents. These findings support previous suggestions that metals, such as iron, contaminating crocidolite may be implicated in the development of malignant neoplasia. (42 refs)

78-2502 **Chronic Effects of Ingested Asbestos in Rats.** (Eng) Cunningham, H. M. (Health Protection Branch, Health and Welfare, Ottawa, Ontario, Canada); Moodie, C. A.; Lawrence, G. A.; Pontefract, R. D. *Arch Environ Contam Toxicol* 6(4): 507-513; 1977.

Two lifetime experiments, one using 20 male Wistar rats and one using 80 rats, were performed to determine the effects of chronic po administration of chrysotile asbestos on cancer induction. Half the rats in each study were fed a diet containing 1% asbestos. In the first experiment there were one benign tumor and six malignant tumors in the treated rat compared to one benign and one malignant tumor in the controls. There were 36 nonneoplastic lesions in controls and 34 in the treated group. In the second experiment, there were 38 benign and 11 malignant tumors in the treated groups compared to 37 benign and 11 malignant tumors in the controls. There were 327 nonneoplastic lesions in controls and 324 in the treated rats. In a third experiment, 10/20 rats were fed a 1% asbestos diet for 6 wk, and various tissues and blood were examined for the presence of asbestos fibers. The highest levels of asbestos occurred in the omentum (9.66×10^6 fibers/g vs 1.08×10^6 fibers/g in controls), followed by the brain, lung, liver, blood, and kidney. It is concluded that trace amounts of ingested asbestos can penetrate the walls of the gastrointestinal tract of rats; there is insufficient evidence that these fibers can cause cancer. (20 refs)

78-2503 **Ultrastructure of the Lung in the Rat Following Exposure to Crocidolite Asbestos and Quartz.**

Eng) Miller, K. (Natl. Res. Inst. Occupational Diseases, outh African Medical Res. Council, Johannesburg 2000, S. frica); Webster, I.; Handfield, R. I.; Skikne, M. I. *J Pathol* 24(1): 39-44; 1978.

he effects of crocidolite asbestos and quartz on alveolar acrophages and the subsequent fibrogenic reaction in the ng were studied in male Wistar rats exposed to asbestos ,350 fibers/cm^3) or quartz particles (11 mg/m^3) for 8 hr/ ay, 5 days/wk. The animals were killed after 5-7 mo and e lungs prepared for examination. Lung tissue from rats posed to either substance demonstrated thickening of the terstitial tissue and the presence of collagen fibers. Aggre- ates of macrophages in the alveolar spaces were a dominant ature of asbestos-exposed rats. All macrophages were ma- re cells, indicating that the asbestos was nontoxic. Rats posed to quartz did not have aggregated macrophages in e alveolar spaces, and many macrophages showed a charac- ristic pattern of vacuole formation. Other cells contained tracellular membranous lamellated bodies, similar to those und in Type II pneumocytes. Cells containing lamellated odies were also found in the interstitial tissue. Plasma cells ere present in lung specimens from quartz-dusted rats. hese findings suggest that the two mineral dusts have differ- t biological effects on the macrophage and on the develop- ent of pulmonary fibrosis. (34 refs)

-2504 **Mass and Number of Fibres in the Pathogenesis of Asbestos-related Lung Disease in Rats.** (Eng) avis, J. M. (Inst. Occupational Medicine, Roxburgh Place, dinburgh EH8 9SU, Scotland); Beckett, S. T.; Bolton, R. ; Collings, P.; Middleton, A. P. *Br J Cancer* 37(5): 673-688; 978.

he effects of both fiber number and fiber mass in asbe- os-related lung disease were examined. Five groups of white PF rats of the Han strain were exposed to preparations of ree commercially used types of asbestos (chrysotile, ocidolite, and amosite) for 7 hr/day, 5 days/wk, for a total 224 days during a 1-yr period. Animals were killed 12 and 3 mo and 860 days after the start of exposure. Chrysotile ust produced significantly more lung fibrosis than either nphibole type, even when the fiber numbers in the dust ouds were similar. All malignant pulmonary neoplasms denocarcinomas, squamous carcinomas) occurred in ani- als treated with chrysotile. Only two mesotheliomas were und, one solitary spindle-cell tumor in the pleural cavity an animal treated with crocidolite and an abdominal meso- elioma in an animal that had inhaled chrysotile. When fiber ngth distributions were calculated using a scanning electron icroscope, it was found that the chrysotile clouds contained any more fibers >20 μM long than either of the other ouds. The results, therefore, support previous suggestions at long asbestos fibers are more dangerous than short ones, id they indicate that neither a single mass standard nor fiber umber standards are satisfactory. (32 refs)

Medicine, Ohio State Univ., Columbus, OH, 43210); Newman, H. A.; Allison, D. K.; Hart, R. W. *Fed Proc* 37(6): 1645; 1978. (1 ref)

78-2506 **Metabolism and Tissue Binding of Diethylstilbestrol (DES) in the Pregnant Rat: An In Vitro Study (Meeting Abstract).** (Eng) Miller, R. K. (Dept. Obstetrics and Gynecology, Univ. Rochester, Rochester, NY); Laveman, L. B.; Reich, K. A. *Teratology* 17(2): 33A; 1978. (no refs)

78-2507 **Localization of ^{3}H-Estradiol-17β in Diethylstilbestrol-induced Adenosis.** (Eng) Kalland, T. (Inst. Anatomy, Univ. Bergen, Arstadvn 19, Bergen, N-5000, Norway); Fossberg, T. M.; Forsberg, J. G. *Obstet Gynecol* 51(4): 464-467; 1978.

The uptake and distribution of ^{3}H-estradiol-17β was studied in normal and diethylstilbestrol (DES)-treated mice. Newborn females were given five daily injections of 5 μg DES beginning within 24 hr of birth. At 6 mo, all estrogenized animals were ovariectomized and, 24 hr later, each animal received 2 μCi/kg ^{3}H-estradiol-17β sc. The animals were sacrificed 2 hr later. A heavy labeling was noted in the uterine tissue of control animals; stromal and epithelial cells were equally labeled. Estrogenized animals showed the same results in specimens taken from the uterus proper. No difference between control and estrogenized animals was noted in specimens from the uterine cervix and upper vagina; however, the overall picture was of weaker labeling than in the uterus proper. Areas of adenosis in the estrogenized animals showed the same intensity of labeling as the epithelial cells in the uterus. Autoradiograms of these regions showed a marked labeling over the epithelial cells and a nuclear concentration of grains. It is concluded that the adenosis cells in mice are target cells for estrogen. Thus, the development of adenosis in mice and clear cell adenocarcinoma in humans at puberty may be due to the hormonal action of estrogens. Estrogen exposure, including oral contraceptive use, should be avoided by women with vaginal adenosis. (22 refs)

78-2512 **Estrogenic Activity In Vivo and In Vitro of Some Diethylstilbestrol Metabolites and Analogs.** (Eng) Korach, K. S. (Lab. Environmental Toxicology, Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC, 27709); Metzler, M.; McLachlan, J. A. *Proc Natl Acad Sci USA* 75(1): 468-471; 1978.

Three diethylstilbestrol (DES) metabolites and three DES analogs were tested for their estrogenic activity in vivo and in vitro. The metabolites were β-dienestrol, DES α,α′-epoxide (DES epoxide), and α,α′-dihydroxy DES (dihydroxy-DES); the analogs were α-dienestrol, DES-dihydroxydiethylphenanthrene (DES phenanthrene), and 1-(α-ethyl-4α-hydroxyphenyl)indanyl-5-ol (indanyl-DES). As determined by the immature mouse uterine wt bioassay in CD-1 mice, the in vivo estrogenicity of the compounds was in the order DES > α-dienestrol ⩾ DES epoxide > indanyl-DES > dihydroxy-DES > β-dienestrol > DES phenanthrene. In vitro competition equilibrium binding experiments for the uterine estradiol cytosol receptor yielded a similar order of estrogenicity, except that indanyl-DES had a binding affinity comparable to that of DES and α-dienestrol. Sucrose gradient analysis of the competition preparations demonstrated the displacement of ^{3}H-estradiol from the receptor peak. This displacement was receptor-specific, and it correlated with the equilibrium binding concentrations. In addition, the most hormonally active substances had the greatest effect on the association rate reaction of estradiol and the cytoplasmic receptors. These results are discussed in relation to the metabolism and action of DES. (22 refs)

78-2513 **In Utero Exposure to DES. Evaluation and Followup of 199 Women.** (Eng) Fowler, W. C. (Dept. Obstetrics and Gynecology, Div. Gynecologic Oncology, Univ. North Carolina, Chapel Hill, NC, 27514); Edelman, D. A. *Obstet Gynecol* 51(4): 459-463; 1978.

A total of 180 females with known in utero exposure to diethylstilbestrol (DES) and 19 with histories and/or pelvic examinations suggestive of DES exposure were examined. The subjects ranged in age from 12 to 30 yr (mean, 21.6 yr). Only 13.6% had normal colposcopic findings in the vagina and cervix. The incidence of colposcopically detected lesions was not related to the trimester of DES exposure, the patient's age, use of oral contraceptives, or presenting symptoms. Colposcopically directed biopsies of abnormal or suspicious areas revealed 36 cases of cervical intraepithelial neoplasia (CIN), Grade 1 lesions, and 8 cases of CIN, Grade 3 lesions. A total of 28 patients had vaginal adenosis and 62 had one or more of the following cervical abnormalities: cervical bands, cock's combs, and hoods. Areas of punctation, mosaic patterns, white epithelium, and keratosis were not considered areas of adenosis. No cases of clear cell adenocarcinoma were noted. It is suggested that women with in utero DES exposure are at a greater risk than nonexposed women for the development of squamous neoplasia. (15 refs)

78-2514 **Endometrial Carcinoma Following Estrogen Therapy for Breast Cancer. Report of Three Cases.** (Eng) Khandekar, J. D. (Dept. Medicine, Evanston Hosp., 2650 Ridge Ave., Evanston, IL, 60201); Victor, T. A.; Mukhopadhyaya, P. *Arch Intern Med* 138(4): 539-541; 1978.

Three women developed endometrial carcinoma after treatment of their breast cancer with diethylstilbestrol (DES). The first was a 61-yr-old woman who had undergone bilateral salpingo-oophorectomy 29 yr prior to the development of breast cancer. DES therapy (15 mg/day, po) was initiated when bone and liver scans demonstrated metastatic carcinoma. Seven years later, the endometrial carcinoma was diagnosed. The second woman was 69 yr old when she underwent right radical mastectomy for carcinoma in her right breast; 28/29 axillary and 6 right subclavian lymph nodes were positive. DES (15 mg/day, po) was administered upon recurrence in the right axilla 1 yr later. Hysterectomy and bilateral salpingo-oophorectomy, performed 1 yr later upon suspicion of a left ovarian tumor, revealed the endometrial carcinoma. The third was a 64-yr-old woman who received DES (15 mg/day, po) for pleural effusion 2.5 yr after modified radical mastectomy for a tumor. Endometrial biopsy 32 mo after initiation of therapy revealed the carcinoma. These findings support the hypothesis that endometrial carcinoma an occur in breast cancer patients receiving DES therapy. 17 refs)

8-2515 **Exogenous Oestrogens and Ovarian Cancer (Letter to Editor).** (Eng) Hoover, R. (Environ-nental Epidemiology Branch, NCI, Bethesda, MD, 20014); raumeni, J. F.; Gray, L. A. *Lancet* 1(8059): 325-326; 1978.

n a clarification of a previous communication, it is emphazed that not all exogenous estrogens were claimed to be ssociated with ovarian cancer; only diethylstilbestrol DES) has a relative risk of 30.0. When adjustments re made for the prevalence of oophorectomy in the eneral population, this value does not change. Although nese findings were based on only a few cases, the magniude of the risk plus experiments in dogs warrant etiogical consideration of DES in ovarian cancer in postenopausal women. (5 refs)

8-2516 **Hormone-dependent Mammary Tumors in Strain GR/A Mice. IV. Origin and Progression.** Eng) Aidells, B. D. (Dept. Molecular Biology, Univ. Cali-rnia, Berkeley, CA, 94720); Daniel, C. W. *J Natl Cancer ıst* 60(6): 1345-1350; 1978.

wo types of hormone-dependent mammary tumors that ocir in strain GR/A mice, ie, those that appear during pregancy [pregnancy-dependent mammary tumors (PrDT)] and iose induced by treatment with progesterone (P) and estroen (E) [P + E-dependent mammary tumors (P + E-DT)], ere compared in terms of serial transplantation, response pregnancy, and histology. Both types originated as ductal yperplasias. When the P + E-induced ductal hyperplasias ere transplanted into the parenchyma-free mammary fat ıd, their behavior was similar to that of pregnancy-induced ımors. P + E-induced ductal hyperplasias gave rise to ducl outgrowths in the virgin host and to PrDT in the pregnant ost; this indicated that the ductal hyperplasias are preneoastic lesions in strain GR mice. Because no spontaneous rogression of tumors to a pregnancy-independent state had ccurred after eight to nine serial transplant generations in rDT lines, attempts were made to induce this state by forced reeding. In contrast to nontransplanted PrDT, which usual- require three to five forced breedings of mice to inıce pregnancy independence, six to eight matings were eeded to induce progression to pregnancy indepenence in the transplanted lines. The results suggest that rial transplantation in the cleared fat pad may select r less-neoplastic variants. (20 refs)

8-2517 **Oral Contraceptives and Focal Nodular Hyperplasia of the Liver. Two Case Reports with Electron-Microscopic Studies.** (Eng) Balazs, M. (Dept. Pathology, Janos Hosp., Diosarok u. 1, H-1125 Budapest, Hungary); Gergely, R.; Kostic, S. *Acta Hepatogastroenterol (Stuttg)* 25(2): 111-118; 1978.

Case reports are presented for two women (26 and 36 yr old) who developed focal nodular hyperplasia of the liver and who had been taking oral contraceptives for 2 and 6 yr, respectively. In both cases the tumor was detected during cholecystectomy for cholelithiasis. The patients had no other symptoms. Physical examination did not reveal any pathological changes, and laboratory tests were negative. Biopsy specimens from one of the tumors were examined by electron microscopy. Paracrystalloid inclusions were found in the mitochondria of the tumor cells. The most prominent feature seen by electron microscopy was abnormal vascularization in the tumor tissue. It is hypothesized that abnormal regeneration similar to cirrhosis in the circumscribed areas of the liver was responsible for the disturbed microcirculation. The rich vascularization and the special vascular structure of these tumors may induce severe hemorrhage. Whenever possible, radical removal of the tumor is suggested, and oral contraceptives should be stopped because of the danger of recurrence or malignant transformation of the tumor. (50 refs)

78-2518 **Distribution of Sex Hormones in Patients with Carcinoma of the Prostate.** (Rus) Kislyakova, N. D. (Hormonal Lab., Scientific Res. Inst. Oncology, Rostov, USSR); Luntovskaya, V. A.; Polyanichko, M. F.; Volovelsky, I. Z. *Vopr Onkol* 24(1): 86-89; 1978.

Sex hormone levels were studied in 84 patients with prostatic carcinoma and 24 healthy controls. The patients and controls were divided into three groups: 50-59 yr (15 patients and 10 controls), 60-69 yr (37 and 7, respectively) and 70-80 yr (33 and 7). The daily urinary excretion of testosterone was decreased in patients from the first two age groups (39.15 and 15.28 μg/day, respectively, compared to 60.67 and 20.7 μg/day in controls) and increased in the patients in the third age group (12.61 μg/day, compared to 9.13 μg/day in controls). Urinary excretion of total 17-ketocorticosteroids was decreased only in patients from the 50- to 59-yr age group (7.2 mg, compared to 12.3 in controls). (15 refs)

78-2519 **Benign Hepatic Lesions in Women Taking Oral Contraceptives.** (Eng) Davis, T. J. (Dept. Radiology, Presbyterian Hosp., 8200 Walnut Hill Lane, Dallas, TX 75231); Berk, R. N. *Gastrointest Radiol* 2(3): 213-219; 1977.

The literature on benign hepatic lesions associated with oral contraceptives is reviewed, with emphasis on clinical symptoms and on diagnosis by angiography and the radionuclide scan. In addition, four previously unreported cases are described. Patient 1 was a 26-yr-old woman on Orthonovum 1/80 for 7 yr who on routine examination, was found to have a palpable midepigastric abdominal mass. Histological examination of the resected hepatic tissue revealed focal nodular hyperplasia. The second patient was a 23-yr-old woman also on contraceptive medication for 7 yr (Orthonovum 1/80, 3 yr; Ovulen 21, 6 mo; Demulen, 3 yr) who presented with acute abdominal pain, nausea, and vomiting. A right hepatic lobectomy was performed, and a 6-cm hepatic adenoma with surrounding hematoma was removed. Patient 3, a 41-yr-old woman on Ovulen 21 for 6 yr, also presented with pain. Histological examination of the tissue removed on left hepatic lobectomy revealed a hepatic adenoma with two foci of nodular hyperplasia and a retention cyst in the adjacent tissue. Patient 4, a 38-yr-old woman on Ovulen 21 for 4.5 yr, was found to have a liver nodule when she underwent surgery for a suspected ovarian tumor. The histological diagnosis was focal nodular hyperplasia. All four patients did well postoperatively, and they were followed with radionuclide scans. (55 refs)

78-2520 **Size of Random Samples for Aflatoxin Determination in Peanuts.** (Ger) Waibel, J. (NATEC Gesellschaft für naturwissenschaftlich-technische Dienste mbH, Behringstrasse 154, D-2000 Hamburg 50, W. Germany). *Dtsch Lebensm Rundsch* 73(11): 353-357; 1977.

Analysis of 500 peanut samples for aflatoxin content indicated that for random sampling in factory control, the minimum sample size should be at least 5 kg. For official survey checking, the accumulation of data from each individual producer is adequate. (8 refs.)

78-2521 **Conversion of Aflatoxin B_1 to Aflatoxin D_1 in Ammoniated Peanut and Cottonseed Meals.** (Eng) Lee, L. S. (Southern Regional Res. Center, Agricultural Res. Service, US Dept. Agriculture, New Orleans, LA, 70179); Cucullu, A. F. *J Agric Food Chem* 26(4): 881-884; 1978.

Cultured and spiked peanut and cottonseed meals, high in aflatoxin, were ammoniated under laboratory conditions paralleling those employed for the model ammoniation of pure aflatoxin B_1, as well as under conditions used in commercial detoxification with ammonia. In the model reaction, 10% aflatoxin B_1 remained after ammoniation and 10% was converted to aflatoxin D_1. In all ammoniation studies conducted on spiked and cultured peanut and cottonseed meals, an av of 0.36% aflatoxin B_1 was converted to aflatoxin D_1, and an av of 0.37% of the B_1 compound remained unreacted. (10 refs)

78-2522 **Toxic Responses in Gerbils Treated Topically with Aflatoxin B_1 and Dimethylformamide.** (Eng) Llewellyn, G. C. (Dept. Biology, Virginia Commonwealth Univ., Richmond, VA, 23284). *Bull Environ Contam Toxicol* 19(6): 747-754; 1978.

The effects of topically applied aflatoxin B_1 (AFB_1) and/or dimethylformamide (DMF) were studied in adult male and female Mongolian gerbils. The animals were painted with DMF alone (0.1 ml, 1x/wk or 2x/wk) or AFB_1 dissolved in DMF (500 μg/0.1 ml DMF, 1x/wk or 2x/wk) over a 35-day period. Animals were sacrificed after 174 days, and the liver, kidney, bladder, and treated skin were examined histologically. No pathological responses were detected in any of the organs examined. In the male treatment groups, the control animals showed the highest gain in body wt. The males treated with AFB_1-DMF 2x/wk failed to gain wt initially, showed fluctuations over the duration of the study, but by 120 days had attained a body wt similar to that of the control group. AFB_1 seems to have an effect on membranes and this effect may influence the animals' response to DMF and cause the wt gain differences. It is concluded that gerbils do not absorb appreciable levels of AFB_1 through the skin and, therefore, do not attain the necessary levels of AFB_1 or activated product to result in toxic or carcinogenic effects. (21 refs)

78-2523 **Metabolism and Toxicokinetics of Aflatoxin B_1 in the Monkey, Rat and Mouse: Indications of Species Susceptibility (Meeting Abstract).** (Eng) Wong, Z. A. (Dept. 78-2524 **Modification of Hepatotoxic Effects of Aflatoxin B_1 in Rabbits by Immunization.** (Eng) Ueno, I. (Univ. Tokyo, Tokyo, Japan); Chu, F. S. *Experientia* 15(1): 85-86; 1978.

The usefulness of immunization with bovine serum albumin (BSA)-aflatoxin B_1 conjugate against aflatoxicosis was tested in female albino rabbits. Six weeks after immunization with BSA-aflatoxin B_1 conjugate (210 μg/rabbit), which contained 13 moles of aflatoxin B_1/mole of BSA, immunized and control animals were challenged with a single dose of aflatoxin B_1 at LD_{50} or slightly higher doses. All immunized rabbits were protected from the acute toxic effect, but the expected mortality rate was seen in the unimmunized rabbits. Protection was not absolute, however, since immunized rabbits challenged with twice the LD_{50} dose 17 days after the first challenge showed a greater than 50% mortality. Serum isocitric dehydrogenase activity remained near normal following challenge of the immunized rabbits, but it increased significantly in the control rabbits after they received aflatoxin B_1. Histological examination of the liver of immunized rabbits that survived the challenge showed no abnormality. These results indicate that immunization might be used prophylactically against aflatoxicosis, but it is not known whether imnunization might inhibit the aflatoxin B_1-induced hepatocarcinogenic effect in animals. 8-2527 **A Scanning Electron Microscopic Study of IAA-induced Tumours in Bean (*Phaseolus vularis* L.) Embryos.** (Eng) Sen, S. (Dept. Biology, Bethune-Cookman Coll., Daytona Beach, FL, 32015); Stevenson, E. . *Cytobios* 18(69): 27-36; 1977.

ndole-3-acetic acid (IAA)-induced tumors in bean (*Phaseous vulgaris*) embryos were studied electron microscopically. The tumors formed between the epicotyl and radicle, and hey produced total rupture and ultimate destruction of the pidermis. The hypocotyl portion showed enlarged, filamenous, thin-walled parenchymatous tissue along the tumor surace, and the filamentous cells showed pustules on the walls. The leaf of the tumorous embryo gradually atrophied with ime, indicating that IAA inhibits epicotyl growth. Furthernore, the stomas demonstrated less crystalline deposition han control embryos. When the IAA was depleted, epicotyl rowth resumed, indicating that the tumors were IAA-ependent. (9 refs)

8-2528 **Mutagenicity of Flavone Derivatives.** (Eng) Sugimura, T. (Natl. Cancer Center Res. Inst., sukiji, Chuo-ku, Tokyo 104, Japan); Nagao, M.; Matsuima, T.; Yahagi, T.; Seino, Y.; Shirai, A.; Sawamura, M.; latori, S.; Yoshihira, K.; Fukuoka, M.; Kuroyanagi, M. *Proc pn Acad [B]* 53(4): 194-197; 1977.

f several flavone derivatives of plants tested on *Salmonella phimurium* for mutagenicity, kaempferol, quercetin, and alangin had high mutagenic activities and fisetin was weakly utagenic. It is suggested that the hydroxyl groups on e phenyl moiety are essential for mutagenic activity nd that the 3,5,7-trihydroxyflavone structure inhibits is activity. (12 refs)

78-2529 **An Analysis of Meiotic Chromosomes of Inbred Male Mice and Their F_1 Sons After Long-Term Treatment of Sires With Triethylenemelamine.** (Eng) Pecevski, J. (Lab. Radiobiology, Boris Kidric Inst. Nuclear Sciences, Belgrade, Yugoslavia); Maric, N.; Savkovic, N.; Radivojevic, D.; Green, S. *Mutat Res* 54(1): 55-60; 1978.

Male C_3H mice were treated with triethylenemelamine (0.02 and 0.04 mg/kg po for 8 wk), to determine the dose-dependent effects of the chemical on fertility and the induction of chromosomal translocations in these mice and their F_1 offspring. Semisterility and sterility plus reciprocal translocations were noted only in the F_1 males, and the changes occurred to a greater degree in the offspring of mice given the higher dose. (10 refs)

78-2530 **Salbutamol: Lack of Evidence of Tumour Induction in Man (Letter to Editor).** (Eng) Poynter, D. (Allen and Hanburys Res. Ltd., Ware, Herts, England); Harris, D. M.; Jack, D. *Br Med J* 1(6104): 46-47; 1978.

Experimental studies to date on the carcinogenicity of salbutamol (SB, or albutamol, a β-adrenoreceptor stimulant) are discussed. Early work with soterenol, another β-adrenoreceptor stimulant, revealed mesovarian leiomyoma formation in Sprague-Dawley rats. Extension of these tests with salbutamol sulfate revealed similar results. When Charles River CD rats were given a max of 50 mg/kg SB, benign leiomyomas resulted. SB was not oncogenic in mice at daily po doses 2,000 times the human daily po intake; it was not mutagenic in vitro at doses 1,000,000 times its effective concentration. Because mesovarian leiomyomas are extremely rare in humans, any increase in their frequency as a result of SB treatment would have been noticed. Higher doses, such as those that cause animal tumors, would produce intolerable cardiovascular effectors and muscle tremor. Since there is little evidence that SB is carcinogenic and it is a selective β_2-adrenergic bronchodilator, there is no rational basis for discontinuing its use. In the US, clinical trials have been halted pending the results of new toxicity data. (2 refs)

78-2531 **Prior Psychiatric Treatment and the Development of Breast Cancer.** (Eng) Overall, J. E. (Univ. Texas Medical Branch, Galveston, TX). *Psycho Pharmacol Bull* 14(1): 19-20; 1978.

The records of 377 women with breast cancer and 236 women with other cancers were studied for prior psychiatric treatment with major neuroleptic drugs, which increase prolactin levels. Prolactin plays a key role in virus- and carcinogen-induced mammary tumors in rodents. Only 1.33% of the breast cancer patients and 1.27% of the other cancer patients had a prior psychiatric diagnosis, and none had a prior diagnosis of schizophrenia. It is concluded that in terms of risk/benefit ratio, the risk of breast cancer should not be a major consideration in the clinical use of psychotherapeutic drugs. (no refs)

78-2532 **Mutagenicity of Aclacinomycin A and Daunomycin Derivatives.** (Eng) Umezawa, K. (Dept. Molecular Oncology, Inst. Medical Science, Univ. Tokyo, Shirokanedai, Minato-ku, Tokyo 108, Japan); Sawamura, M.; Matsushima, T.; Sugimura, T. *Cancer Res* 38(6): 1782-1784; 1978.

The mutagenicity of the antitumor antibiotics aclacinomycin A and daunomycin and some of their derivatives was investigated using *Salmonella typhimurium* strain TA98. Neither aclacinomycin A, N-monodemethylaclacinomycin A, nor N-demethylaclacinomycin A was mutagenic in the absence of metabolic activation by the S-9 mix. In the presence of the mix, only N-demethylaclacinomycin A was mutagenic. 1-Deoxypyrromycin, a hydrolysis product of aclacinomycin A, and N-monodemethyl-1-deoxypyrromycin were not mutagenic in the presence or absence of the mix; N-demethyl-1-deoxypyrromycin was mutagenic, but only with metabolic activation. Daunomycin, N-methyldaunomycin, and N-dimethyldaunomycin were highly mutagenic, weakly mutagenic, and nonmutagenic, respectively, both in the presence and absence of the S-9 mix. Aclavinone and daunomycinone, the aglycones of aclacinomycin A and daunomycin, respectively, were not mutagenic either in the presence or absence of the mix. It is concluded that the amino moiety of anthracycline glycosides is essential for mutagenesis. (11 refs)

8-2546 **Mutagenicity of Fume Particles from Stainless Steel Welding.** (Eng) Hedenstedt, A. (Environ. oxicol. Unit, Univ. Stockholm, Stockholm, Sweden); enssen, D.; Lidesten, B. M.; Ramel, C.; Rannug, U.; tern, R. M. *Scand J Work Environ Health* 3(4): 203-11; 1977.

ume particles collected from different welding procedures vere tested for mutagenicity in *Escherichia coli* (the inhibiion zone in *pol A* was compared with that in *pol A*$^+$) nd in *Salmonella typhimurium* strain TA100. Although 10 mutagenicity was found with mild steel welding, mutagenic effect was established with samples from tainless steel welding. This mutagenicity was particularly associated with manual metal arc (MMA) welding and, to a lesser extent, with metal inert-gas welding. The effect was diminished or eliminated in the presence of a liver microsomal metabolizing system (S-9 mix). More-detailed investigations of the MMA samples showed that the mutagenic agent(s) is water-soluble. An increased mutagenicity associated with the induction of frameshift mutations was found with *S. typhimurium* TA98. The same fume sample was used for a mutagenicity test (resistance to 6-thioguanine) in V79 hamster cells. Because of the high toxicity of these welding fume particles, only very low concentrations could be tested, but the increase in mutations was significantly higher then that in control cells. It is suggested that hexavalent chromium may be involved in the mutagenic effect of the welding fumes. (13 refs)

78-2547 **DNA Targets for Carcinogens Within Living Human Bone Marrow Cells (Meeting Abstract).** (Eng) Frenster, J. H. (Dept. Medicine, Stanford Univ., Stanford, CA); Landrum, S. R.; Masek, M. A.; Nakatsu, S. L. *Clin Res* 26(3): 434A; 1978. (3 refs)

78-2548 **Malignant Neoplasms in Rats Fed Lasiocarpine.** (Eng) Rao, M. S. (Dept. Pathology, Northwestern Univ. Medical Sch., 303 E. Chicago Ave., Chicago, IL, 60611); Reddy, J. K. *Br J Cancer* 37(2): 289-293; 1978.

The effects of chronic dietary administration of lasiocarpine, a pyrrolizidine alkaloid, were studied in 20 male F-344 rats fed 50 ppm for 55 wk. Malignant tumors developed in 17/20 animals between 48 and 59 wk. There were 16 liver tumors, 9 angiosarcomas and 7 hepatocellular carcinomas. Other tumors were a malignant adnexal tumor of the skin (1 rat, that also had an angiosarcoma) and a lymphoma (1 rat). Metastasis to the lungs was observed in four animals with angiosarcomas and one animal with a hepatocellular carcinoma. An angiosarcoma from one animal was successfully transplanted through four generations. Previous studies with repeated ip lasiocarpine injections and with other alkaloids administered by various routes gave rise to other histiogenetic types of liver tumors. These differences illustrate the effect of the dose and mode of administration of various alkaloids on the susceptibility of different cell types in a given target organ. (10 refs)

78-2549 **Carcinogenic and Mutagenic Activities of Milk from Cows Fed Bracken Fern (*Pteridium aquilinum*).** (Eng) Pamukcu, A. M. (Div. Clinical Oncology, Dept. Human Oncology, Univ. Wisconsin Center Health Sciences, 1300 University Ave., Madison, WI, 53706); Erturk, E.; Yalciner, S.; Milli, U.; Bryan, G. T. *Cancer Res* 38(6): 1556-1560; 1978.

The carcinogenicity, toxicity, and mutagenicity of the milk of Brown Swiss cows fed bracken fern (BF) and hay grain (HG: normal diet) were determined. The BF-fed cows were fed 1 g/kg/day for a total biennial BF intake/cow of 218-252 kg. The milk was fed to male and female Norwegian strain rats as either fresh or freeze-dried powdered milk mixed with grain. Of the rats fed milk from BF-fed cows, 9/34 fed whole milk and 11/56 fed powdered milk developed small intestinal, kidney, or urinary bladder carcinomas within 117 wk, vs 0/70 rats fed either whole or powdered milk from cows receiving a HG diet and 9/20 rats fed a basic grain diet. The pentane, methanol, benzene, diethyl ether, ethyl acetate and residue fractions of milk from BF- and HG-fed cows were prepared. The diethyl ether and ethyl acetate fractions displayed the highest murine acute toxicity. The murine bladder carcinogenicity of prepared fractions was assessed by pellet implantation (20 mg containing 1:3 wt/wt concentrations of each fraction). Diethyl ether fractions from BF-fed cows induced bladder carcinomas in 10/24 mice, compared with 3/19 mice fed the same fraction from HG-fed cows. The pentane, methanol, chloroform, and chloroform:methanol fractions of milk from BF- and HG-fed cows were tested for mutagenicity in *Salmonella typhimurium* strains TA98 and TA100. Only the chloroform:methanol fraction from BF-fed cows was mutagenic, and then only with TA100. Cystoscopic examination of the BF-fed cows revealed urinary bladder papillomas in all animals (4); no changes were noted in cows fed HG. The significance of these results in terms of the human risk of gastointestinal tract or urinary bladder cancer following ingestion of milk from BF-fed cows is not known. (18 refs)

8-2560 **Occurrence of Methylguanidine and Agmatine, Nitrosatable Guanidino Compounds, in Foods.** Eng) Kawabata, T. (Dept. Biomedical Res. on Food, NIH, hinagawa-ku, Tokyo 141, Japan); Ohshima, H.; Ino, M. *J gric Food Chem* 26(2): 334-338; 1978.

sing a recently developed method for the determination and lentification of some basic guanidino compounds in foods, e nitrosated methylguanidine (MG) and nitrosated agma- ne (AG) contents of various fresh and processed foods were etermined. The results were confirmed by gas chromatogra- hy-mass spectrometry. The MG content of fresh foods inged from not detectable (ND) in most foods to 2.5 mg/kg chicken. It appears unlikely that MG occurs naturally in esh foods in the high concentrations reported previously. xcept for smoked-dried fish products, none of the processed ods tested contained more than trace amounts of MG, the noked-dried fish products contained from 18.1 to 178 g/kg MG, although it seems unlikely that these pro- ucts are responsible for the high incidence of gastric ancer in Japan. The AG levels in fresh foods ranged om ND to 18 mg/kg in most cases, but they were onsiderably higher (up to 224 mg/kg) in abalone and op-shell muscle. Most processed foods also contained nly small amounts of AG, although some salted- ried seafood products contained levels up to 650 g/kg. In the processed foods, there was no sign of deteriora- on with high AG concentrations. (16 refs)

8-2561 **Inhibition of Nitroso Chemical Carcinogen Activation of Rat Liver Guanylate Cyclase Activi- / by Antitumor Agents (Meeting Abstract).** (Eng) Vesely, . L. (Dept. Medicine, Univ. Miami Sch. Medicine, Miami, L); Levey, G. S. *Clin Res* 26(3): 537A; 1978. (no refs)

3-2562 **Experimental Cancer of the Stomach Induced in Rats with N-Methyl-N′-nitro-N-ni- osoguanidine.** (Jpn) Nishizato, Y. (Dept. Internal Medi- ne, Tokyo Medical Coll., Shinjuku-ku, Tokyo 160, Japan). *okyo Ika Daigaku Zasshi* 35(5): 759-770; 1977.

umor development was studied in Wistar rats fed N-meth- -N′-nitro-N-nitrosoguanidine (167 μg/ml) continuously in e diet. The majority of the gastric tumors developed in the sser curvature of the glandular stomach, and many were evated. Histologically, most tumors were adenocarcinomas that invaded as deep as the serosa. There did not appear to be any correlation between tumor formation and degree of intestinal epithelial metaplasia. In some animals, the right gastric artery, the gastroduodenal artery, and the gastroepiploic artery were ligated before carcinogen administration. Animals thus treated had striking erosions and proliferation of the pit epithelium and prominent upward and downward adenomatous hyperplasia. (27 refs)

78-2563 **Chemically Induced Gastric Carcinogenesis of the Rat after Vagotomy and Resection.** (Ger) Rumpf, P. (Chirurgische Universitatsklinik A, Moorenstrasse 5, D-4000 Dusseldorf, W. Germany); Schacht, U.; Palomba, P.; Kremer, K.; Schmitz, H.; Borchard, F. *Z Gastroenterol* 16(2): 85-94; 1978.

The effects of truncal vagotomy with pyloroplasty and Billroth II (B-II) gastric resection without Braun's anastomosis on the carcinogenic effect of N-methyl-N′-nitro-N-nitrosoguanidine (MNNG) were studied in inbred male Wistar rats. Six-week-old animals received drinking water containing 30 or 100 mg/liter MNNG ad libitum for 480 days, and they were then sacrificed. Vagotomy or gastric resection was performed after the first 7 wk of treatment. The controls received MNNG only. The first carcinoma was discovered on day 392 in a control rat treated with 100 mg/liter. Malignant gastric tumors (mainly tubular and papillary adenocarcinomas plus 2 carcinosarcomas and 2 signet ring cell carcinomas) were found in 6/40 control rats treated with 30 mg/liter, in 21/40 controls treated with 100 mg/liter, in 2/22 vagotomized rats treated with 30 mg/liter, in 11/21 vagotomized rats treated with 100 mg/liter, in 8/16 B-II rats treated with 30 mg/liter, and in 15/18 B-II rats treated with 100 mg/liter. The findings indicate that the incidence of gastric carcinoma was significantly higher in B-II rats than it was in the controls, but vagotomy did not increase the incidence. (17 refs)

78-2568 **Phenotypic Lag and Mutation to 6-Thioguanine Resistance in Diploid Human Lymphoblasts.** (Eng) Thilly, W. G. (Toxicology Group, Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Room E18-666, Cambridge, MA, 02139); Deluca, J. G.; Hoppe, H.; Penman, B. W. *Mutat Res* 50(1): 137-144; 1978.

A mutation assay at the hypoxanthine-guanine phosphoribosyltransferase (HGPRT) locus, expressed as 6-thioguanine resistance (6TG-r), was used to determine the time required for expression of the mutant phenotype after treatment of diploid human lymphoblasts with various mutagens. 6TG mutants appeared 7 and 13 generations after exposure of the cells for 24 hr to 37.5 and 50 μM methylnitrosourea (MNU), respectively; 6, 7, and 9 generations after exposure to 0.075, 0.15, and 0.225 μM N-methyl-N′-nitro-N-nitrosoguanidine (MNNG); 15 generations after exposure to 50 μM 5-bromodeoxyuridine; and 16, 16, and 15 generations after exposure to 0.625, 1.25, and 2.50 μM ICR-191, a substituted, acridine half-mustard. For MNU and MNNG, the length of the phenotypic lag appeared to be concentration-dependent. It is hypothesized that expression of 6TG-r may require the removal of essentially all preexisting HGPRT molecules via division, dilution, and protein turnover. Each potential mammalian cell mutation assay should be characterized carefully with regard to the length and possible variability of phenotypic lag. (30 refs)

78-2571 **The Effect of Iodoacetamide-induced Fundic Ulcers on Gastric Carcinogenesis Produced by N-Methyl-N′-nitro-N-nitrosoguanidine in Rats.** (Eng) Majima, S. (First Dept. Surgery, Kyoto Prefectural Univ. Medicine, Kyoto 602, Japan); Fukushima, M.; Fujita, Y.; Ouchi, T. *Tohoku J Exp Med* 123(4): 381-388; 1978.

The effect of iodoacetamide (IAM)-induced ulcers on the subsequent development of gastric carcinoma produced by N-methyl-N′-nitro-N-nitrosoguanidine (MNNG) was examined in male Wistar rats. IAM (0.1% soln) was given in the drinking water for 8 wk. MNNG (50 or 100 mg/liter in the drinking water) was given from weeks 6 to 26. Two additional groups of rats were given IAM or MNNG alone. Fifty-six of the 62 ulcers induced by IAM (alone or with MNNG) were located in the fundic gland area along the limiting ridge. There were no ulcers in the rats treated with MNNG alone. The incidence of fundic carcinoma was 16% in the groups treated with IAM + MNNG, 0% in the group treated with MNNG alone. The incidence of pyloric gland carcinoma was 18% in the groups treated with IAM + MNNG, 54% in the group treated with MNNG. No tumors were found in the group treated with IAM alone. These results indicate that if an ulcer is present, carcinoma develops even in the fundic mucosa, which is usually resistant to the carcinogenic stimulation of MNNG. It is concluded that gastric ulcer predisposes to the development of gastric carcinoma. (14 refs)

8-2576 **Chemical Induction of Unscheduled DNA Synthesis in Human Skin Epithelial Cell Cultures.** Eng) Lake, R. S. (Dept. Pathology, Children's Hosp. Medical Center, Akron, OH, 44308); Kropko, M. L.; Pezzutti, M. R.; Shoemaker, R. H; Igel, H. J. *Cancer Res* 38(7): 2091-2098; 1978.

A semiquantitative in vitro method for measuring chemical nduction of unscheduled DNA synthesis (UDS) was deveoped to evaluate the range of chemical sensitivity and DNA epair response of human skin epithelial cells. Cryopreserved oreskin epithelial cells were grown from explants and replanted in replicate culture wells. The cultures were then reated for 3 days in arginine-deficient medium and further nhibited in S-phase DNA synthesis by a 2-hr hydroxyurea reatment (10 μM). Carcinogen and ^{3}H-labeled thymidine were added simultaneously, and UDS was accumulated over a 24-hr incubation period determined by direct scintillation counting of acid-precipitable whole-cell radioactivity. All ultimate and proximate carcinogens elicited a doserelated UDS response, as did several classes of procarcinogens. Upon serial subculture of organotypic primary skin cultures, the UDS response induced by the procarcinogen 3-methylcholanthrene decreased in parallel with a decreased ability of cells to metabolize polycyclic hydrocarbons to water-soluble metabolites. Arginine deprivation and hydroxyurea did not impair the ability of epithelial cells to metabolize procarcinogens to DNA-damaging metabolites. It is hypothesized that those procarcinogens that are efficiently metabolized by skin will be detected with UDS as an end point. Similar UDS measurements in a panel of organotypic epithelial cell cultures may provide a relevant technique for detecting specific human carcinogens. (41 refs)

78-2578 **Relative Carcinogenic Effectiveness of N-Methyl-N-nitrosourea (MNUA): and N-Ethyl-N-nitrosourea (ENUA): Quantitative Relation to Alkylation of O-6 of Guanine in DNA (Meeting Abstract).** (Eng) Frei, J. V. (Chester Beatty Res. Inst., Chalfont St. Giles, England); Lawley, P. D.; Swenson, D. H.; Warren, W. *Proc Am Assoc Cancer Res* 19: 169; 1978. (no refs)

78-2579 **Tumor Induction in the Trachea of Hamsters with N-Nitroso-N-methylurea.** (Eng) Yarita, T. (Univ. Tennessee-Oak Ridge Graduate Sch. Biomedical Sciences and Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Nettesheim, P.; Williams, M. L. *Cancer Res* 38(6): 1667-1676; 1978.

The tracheal epithelium of male Syrian golden hamsters was exposed to a 1% soln of N-nitroso-N-methylurea (MNU) once or twice weekly for a period of 5-20 wk (10-30 exposures), and tumor incidence was determined. Carcinomas, all types, were noted in 0/12, 5/12, 10/15, 15/17, and 16/17 hamsters given 10, 15, 20, 25, and 30 twice-weekly exposures, respectively. With 10 exposures, 2/12 hamsters developed benign tracheal tumors. Mean tumor induction time decreased when the frequency of exposure was increased from 50 wk with 10-15 exposures to 28 wk with 25-30 exposures. Tumors were also noted in 20/22 hamsters receiving 20 once weekly exposures; the mean tumor induction time was 35 wk. The major histological types of invasive carcinomas were epidermoid carcinomas (54%), anaplastic large cell and small cell carcinomas (26%), adenocarcinomas (13%), and combined epidermoid-adenocarcinomas (7%). In animals receiving 10-20 twice-weekly exposures, only metaplastic lesions with varying degrees of cellular atypia were noted at the time of the last exposure. (9 refs)

78-2580 **A Comparative Study of the Effects of Various Transplacental Carcinogens in Rabbits.** (Rus) Beniashvili, D. S. (Res. Inst. Oncology, GSSR Ministry Health, Tbilisi, USSR). *Vopr Onkol* 24(3): 77-83; 1978.

Transplacental carcinogenesis was studied in 60 pregnant rabbits. The rabbits were divided into five groups and, 25-26 days prior to parturition, Groups 1-4 were inoculated with ethylnitrosourea (80 mg/kg), methylnitrosourea (40 mg/kg), 7,12-dimethylbenz(a)anthracene (20 mg/kg), and benzo(a)pyrene (30 mg/kg), respectively; Group 5 rabbits served as untreated controls. The offspring of the exposed does were followed for 4 yr: 34/183 rabbits developed 38 tumors (16 tumors were located in the peripheral nervous system, and 12 tumors were located in the kidneys). The number of rabbits developing tumors in the five groups was 16/36, 6/38, 7/35, 5/36, and 0/38, respectively. The av latent period was 436 days in Group 1, 622 days in Group 2, 596 days in Group 3, and 635 days in Group 4. The offspring of the Group 1 does had 8 neurogenic tumors, compared to 1 in Group 2, 4 in Group 3, and 3 in Group 4. (26 refs)

78-2581 **Neoplasms in Purebred Boxer Dogs Following Long-Term Administration of N-Methyl-N-nitrosourea.** (Eng) Denlinger, R. H. (Pathology and Toxicology Res. Unit, Upjohn Co., Kalamazoo, MI, 49001); Koestner, A.; Swenberg, J. A. *Cancer Res* 38(6): 1711-1717; 1978.

The carcinogenicity of N-methyl-N-nitrosourea (MNU) was studied in purebred Boxer dogs, a breed with a high incidence of spontaneous tumors (including brain tumors). Twenty dogs were given weekly iv injections of 5 mg/kg MNU for 36 wk; they were observed for approx 3 yr. Nineteen dogs developed tumors 19-36.5 mo after the first injection; the mean latent period was 30 mo. All tumor-bearing dogs had two or more neoplasms, including metastases, and 14 dogs had tumors of more than one tumor type. Malignant neurinomas of the small intestine were present in 11 dogs, poorly differentiated intestinal sarcomas in 6. Metastasis occurred to the liver, spleen, lymph nodes, lung, and adrenal glands. Two cases of malignant neurinoma developed in the heart, and one each developed in the stomach and colon. Two well-differentiated neurinomas occurred in the small intestine, and one each occurred in a cervical (C_8) spinal root, the stomach, and the colon. Hemangiosarcomas were noted in the spleen of 3 dogs, the heart of 2, a spinal root [the base of the dorsal arch of vertebra T_4 (T_4)] of 1, and a lumbar mass of 1. Three developed hemangiomas of the skin. Malignant. lymphoma developed in the liver of 2, the spleen of 2, and the orbit of 1. One each developed a carcinoma of the intestine and lung; one dog developed a fibrosarcoma of the femur. Because of the high incidence rate, young age at development, and unique tumor types, it is believed that these tumors, especially the neurinomas, resulted from MNU exposure. Although the lack of brain involvement was unexplained, MNU had a neurooncogenic effect on the peripheral nerves of the gastrointestinal tract. (19 refs)

78-2582 **The Stability of Methyl and Ethyl Phosphotriesters in DNA In Vivo.** (Eng) Shooter, K. V. (Chemical Carcinogenesis Div., Inst. Cancer Res., Royal Cancer Hosp., Pollards Wood Res. Station, Nightingales Lane, Chalfont St. Giles, Bucks HP8 4SP, England); Slade, T. A. *Chem Biol Interact* 19(3): 353-361; 1977.

Studies were conducted to determine whether a phosphotriester in DNA is a lesion that is excised and repaired by cellular enzymes in vivo. C57BL male mice were inoculated ip with N-methyl-N-nitrosourea (MNU) or N-ethyl-N-nitrosourea (ENU), and the concentration of alkyl phosphotriesters in the DNA of lung, liver, brain, kidney, spleen, and thymus was determined from the extent of degradation induced in isolated DNA by alkali. The same total dose (2 mg MNU or 4 mg ENU) was given either as a single injection or as weekly injections carried out over 5-20 wk. Methyl phosphotriesters induced in liver, lung, and kidney by the single injection were lost, with a half-life (t1/2) of 7 days; in brain, the t1/2 was 2-3 days. During the multiple MNU injections, t1/2 was 16 days. Ethyl phosphotriesters formed in the DNA of lung, liver, kidney, and brain were much more stable, t1/2 being 10-15 wk. Phosphotriesters formed in the DNA of spleen and thymus disappeared very quickly after the single injection; there was no accumulation of phosphotriesters in the DNA of these tissues during the multiple injections. The relative stability of methyl and ethyl phosphotriesters suggests that these lesions are not excised enzymatically, since it is unlikely that the repair of methylated but not ethylated lesions would occur. The results suggest that phosphotriesters are not lesions that are eliminated by cellular repair enzymes. (23 refs)

78-2583 **Effect of Functional Disturbances of the Thyroid on the Development of Experimental Tumors of Peripheral Nervous System.** (Rus) Beniashvili, D. S. (Scientific Res. Inst. Oncology, Tbilisi, USSR). *Soobshch Akad Nauk Gruz SSR* 87(1): 189-192; 1977.

The role of functional disturbances of the thyroid in the genesis of methylnitrosourea (MNU)-induced tumors of the peripheral nervous system was studied in albino random bred rats and rabbits. All animals received weekly iv injections with NMU (10 mg/kg). Three series of experiments were carried out. Animals in group 1 were given thyroidin (250 mg/kg, daily, for 1.5 yr), animals in group 2 received the antithyroidin drug mercazolyl (5 mg/kg, po, daily, for 18 mo) and animals in group 3 received NMU alone (controls). The incidence of neurogenic tumors was significantly decreased in the animals with hyperfunction of the thyroid: 6/41 rats and 1/12 rabbits in group 1 developed tumors, compared to 23/48 and 7/14, respectively, in group 2, and 15/48 and 3/16, respectively, in group 3. An av latent period of tumor development in groups 1, 2 and 3 was 359.5, 172.1 and 323.4 days, respectively. (12 refs.)

78-2584 **A Study of Chemical Carcinogenesis. 4. Synthesis of the Carbon-14 Labelled Carcinogens 5-Methylchrysene, 2-Methylaniline and 3-Methyl-2-naphthylamine.** (Eng) Weiss, L. (Div. Environmental Carcinogenesis, Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Loy, M.; Hecht, S. S.; Hoffmann, D. *J Labelled Compd Radiopharm* 14(1): 119-131; 1978.

Experimental procedures for synthesizing the ^{14}C-labeled forms of the carcinogens 5-methylchrysene, 2-methyl-iline, and 3-methyl-2-naphthylamine are presented. $^{14}CO_3$ was used to introduce the label. The produres can be used to prepare these compounds in fficient yields for metabolism studies. (26 refs)

-2585 **Tumor-initiating Activity of Fluorinated 5-Methylchrysenes.** (Eng) Hecht, S. S. (Naylor Dana st. Disease Prevention, American Health Foundation, Vallla, NY, 10595); Hirota, N.; Loy, M.; Hoffmann, D. *Canr Res* 38(6): 1694-1698; 1978.

series of fluorinated 5-methylchrysene derivatives was preured and tested for tumor-initiating activity on Ha/ICR male outbred Swiss albino mouse skin. The compounds sted were 1-fluoro-5-methylchrysene, 3-fluoro -5-ethylchrysene, 6-fluoro-5-methylchrysene, 7-fluoro-methylchrysene, 9-fluoro-5-methylchrysene, 11-fluoro-methylchrysene, 12-fluoro-5-methylchrysene, 5,12-methylchrysene, and 12-methoxy-5-methylchrysene. ich compound was assayed at total initiating doses 30 or 100 μg, with promotion thrice weekly by 5 μg of tetradecanoylphorbol acetate. Of the comunds tested, 12-fluoro-5-methylchrysene, 1-fluoro-methylchrysene, 3-fluoro -5- methylchrysene, 5,12-methylchrysene, and 12-methoxy -5- methylchrysene ere less active than 5-methylchrysene, and 6-fluoro-5-meylchrysene, 7-fluoro-5-methylchrysene, 9-fluoro-5-meylchrysene, and 11-fluoro-5-methylchrysene were as otent as 5-methylchrysene. Thus, positions 12, 1, d 3 of 5-methylchrysene are involved in metabolic tivation to the ultimate carcinogen. In this series, e requirements favoring carcinogenicity were a baygion methyl group and an unhindered *peri* position ljacent to an unsubstituted angular ring. (23 refs)

8-2586 **Evidence for Bay-Region Activation of Chrysene 1,2-Dihydrodiol to an Ultimate Carcinoen.** (Eng) Levin, W. (Dept. Biochemistry and Drug Metabosm, Hoffmann-LaRoche Inc., Nutley, NJ, 07110); Wood, . W.; Chang, R. L.; Yagi, H.; Mah, H. D.; Jerina, D. M.; onney, A. H. *Cancer Res* 38(6): 1832-1835; 1978.

n attempt was made to identify the ultimate carcinogenic etabolite of chrysene by testing the compound and its three etabolically possible *trans*-dihydrodiols (at the ,2-, 3,4-, and 5,6-positions) for tumorigenicity in emale CD-1 mice. A single topical application of 0.4, .25, or 4.0 micromoles of each compound was followd 7 days later by twice-weekly applications of 12-O-etradecanoylphorbol-13-acetate for 25 wk. Chrysene ,2-dihydrodiol had approx twice the tumorigenic ctivity of chrysene at all doses tested. Chrysene ,4-dihydrodiol and chrysene 5,6-dihydrodiol had no signifiant tumorigenic activity. 1,2-Dihydroxy-1,2,3,4-tetrahydrochrysene, a compound related to chrysene 1,2-dihydrodiol but without the conjugated nonaromatic double bond at the 3,4-position, had < 25% of its tumorigenic activity. These findings indicate that chrysene 1,2-dihydrodiol is a proximate carcinogenic metabolite of chrysene and that a chrysene 1,2-diol-3,4-epoxide, in which the epoxide group forms part of the bay region in the molecule, is a likely candidate for the ultimate carcinogenic metabolite of chrysene. (24 refs)

78-2587 **Investigations on the Carcinogenic Burden by Air Pollution in Man XVII. Synthesis of the Carcinogen Cyclopenteno(cd)pyrene.** (Eng) Jacob, J. (Biochemisches Institut fur Umweltcarcinogene, Sieker Landstrasse 19, D-2070 Arhrensburg, W. Germany); Grimmer, G. *Zentralbl Bakteriol [Orig B]* 165(3/4): 305-308; 1977.

An experimental procedure for synthesizing the carcinogen cyclopenteno(cd)pyrene (CPP) is described in which acetylpyrene is converted to 1-pyrenylethanol, which in turn is converted to CPP. Previous studies have shown that when CPP is injected sc in mice, it has half the activity of benzo(a)pyrene. (9 refs)

78-2588 **The Inability of Aminoazotoluene to Induce Somatic Crossing-Over or Mutation in *Glycine max* (L.) Merrill.** (Eng) Arenaz, P. (Dept. Biology, Univ. Nevada, Reno, NV, 89557). *Mutat Res* 56(3): 295-298; 1978.

The mutagenicity of aminoazotoluene (AAT) was examined in seeds from soybean (*Glycine max*) varieties T219 and L65-1237, which are heterozygous for the gene combination $Y_{11}y_{11}$ controlling chlorophyll development. The seeds were soaked for varying periods of time in 6, 12.5, 25, or 50 ppm AAT. Leaf analysis indicated that the drug did not increase the frequency of mutation or somatic crossing-over in this system. (10 refs)

78-2589 **o-Aminoazotoluene-induced Tumors in Interscapular Fat in Mice.** (Rus) Kaledin, V. I. (Lab. Cancer Genetics, Inst. Cytology and Genetics, Novosibirsk, USSR); Alekseeva, G. V. *Vopr Onkol* 24(1): 95-98; 1978.

The exposure of A/He and CC57BR mice to o-aminoazotoluene (OAT: 10 mg sc, 1x/mo, 8 doses) induced tumors in the interscapular fat of 49/60 CC57-BR mice. The first tumor appeared 260 days after the initiation of carcinogen administration. Histologically, the tumors were diagnosed as hyperplastic capillary hemangiomas. In addition, 6 mice developed tumors in the femur, 2 in the mesenteric fat, and 1 in the liver (all were typical hemangioendotheliomas). OAT did not induce interscapular fat tumors in A/He, but it did result in the development of liver tumors: 52/60 A/He mice died of liver tumors within 435 days of the start of the experiment. (4 refs)

78-2590 **Murine Liver Tumors Induced by Prenatal and Postnatal Administration of o-Aminoazotoluene.** (Rus) Kolesnichenko, T. S. (Dept. Carcinogenic Agents, Cancer Res. Center, Moscow, USSR); Popova, N. V.; Shabad, L. M. *Biull Eksp Biol Med* 85(2): 199-202; 1978.

The hepatocarcinogenic effect of o-aminoazotoluene (AAT) was studied in the embryos and mature animals of CBA strain mice. Three-mo-old mice or pregnant mice (4-5 days before delivery) were given AAT (12 mg/animal, intragastrically); 12 mo later, the exposed mice and their offspring were sacrificed. Postnatal administration of AAT resulted in liver tumors in 78.7% of the males (compared with 68.5% in controls; CBA males have high frequency of spontaneous liver tumors) and in 89.3% of the females (compared with 11.5% in controls). Administration of AAT to pregnant mice induced liver tumors in 81.8% of their male offspring (35.2% in controls) and in 54.8% of their female offspring (5.3% in controls). Prenatal administration of AAT increased the frequency of malignant liver tumors in males 94.3% vs 57.9% in postnatally exposed males. (11 refs)

78-2594 **3-(Glutathion-S-yl) -N- methyl-4-aminoazobenzene: Metabolic Formation and Affinity for Hepatic Ligandin (Meeting Abstract).** (Eng) Kadlubar, F. F. (Natl. Center Toxicological Res., Jefferson, AR, 72079); Ketterer, B. *Proc Am Assoc Cancer Res* 19: 36; 1978. (no refs)

78-2595 **Carcinomas of the Liver and Forestomach in Mice Ingesting Chlorobenzilate.** (Eng) Reuber, M. D. (NCI Frederick Cancer Res. Center, Frederick, MD, 21501). *Digestion* 16(4): 308-316; 1977.

The max tolerated dose of chlorobenzilate (CB) was given by continuous po administration to both sexes of two hybrid strains of mice, (C57BL/6 x C3HAnf)F_1 (strain X) and (C57BL/6 x AKR)F_1 (strain Y). Seven-day-old mice were administered 215 mg/kg CB in 0.5% gelatin daily by stomach tube. After the mice were weaned at 28 days of age, 603 ppm CB was mixed in the diet and fed ad libitum. The mice were killed after 83 wk. Eight of 17 male mice in each strain developed carcinomas of the liver, and one male mouse in each strain developed a hyperplastic nodule. Hyperplasia and carcinomas of the forestomach were found in 13/18 female strain X mice. Stomach tumors were also present in one male strain X mouse and in one female strain Y mouse. In addition to liver and stomach tumors, there were small numbers of malignant lymphomas and carcinomas of the lung in the CB-treated mice. The liver carcinomas were similar histologically to those observed in mice ingesting other organochlorine pesticides. The forestomach tumors varied from hyperplastic lesions to squamous cell carcinomas with invasion. It is probable that the forestomach lesions go through the various stages of preneoplasia before becoming malignant neoplasms, as do lesions in the liver. (17 refs)

78-2596 **Serum Alpha-Fetoprotein in Experimental Hepatocellular Carcinomas in Rats.** (Eng) Gopal Naidu, N. R. (Dept. Immunopathology, Postgraduate Inst. Medical Education and Res., Chandigarh, India); Aikat, B. K.; Dash, R. J.; Sehgal, S. *Eur J Cancer* 14(3): 295-301; 1978.

Serum α-fetoprotein (AFP) levels were measured by radioimmunoassay during the evolution of chemically induced liver cancer in Wistar rats, and the morphological type of lesion was correlated with AFP synthesis. Animals were given 0.06% 4-dimethylaminoazobenzene (DAB) or 3-methyl-4-dimethylaminoazobenzene (3-Me-DAB) in the diet for 6 mo or 25 μg aflatoxin B_1 po 5 days/wk for 8 wk. Thirty of the animals were fed the two azodyes for only 10 wk. Rats fed the azodyes developed hepatocellular carcinoma (HCC) by 8-24 mo, and they could be divided into two distinct groups, quick and slow responders, on the basis of their capacity to synthesize AFP. The quick responders developed tumors by

8-10 mo, they had high serum AFP values (250-1,110 μg/ml), and their tumors were mainly poorly differentiated HCC. The slow responders developed HCC by 16-24 mo, the tumors were better differentiated, and their serum AFP levels were $< 15\ \mu$g/ml. Both groups showed a biphasic response of AFP during the evolution of HCC. None of the animals in the aflatoxin B_1 group showed a rise in AFP levels of > 1-$2\ \mu$g/ml, and only 2/10 animals developed tumors after 26 mo. Twelve animals that were fed the carcinogenic diet for only 10 wk developed HCC after 20 mo. It is speculated that the transitory AFP elevation in patients with liver cirrhosis or hepatitis indicates a primary reaction and that these patients may eventually develop HCC under the influence of some unknown carcinogenic factors. (19 refs)

78-2598 **Further Improvements in the Hepatocyte Primary Culture DNA Repair Test for Carcinogens: Detection of Carcinogenic Biphenyl Derivatives.** (Eng) Williams, G. M. (Naylor Dana Inst. Disease Prevention, American Health Foundation, 1 Dana Road, Valhalla, NY, 10595). *Cancer Lett* 4(2): 69-75; 1978.

Improvements in the protocol for the detection of autoradiographic unscheduled DNA synthesis (UDS) in hepatocyte primary cultures (HPC) are reported, and they were used to study the relationship between UDS and carcinogenicity in a series of biphenyl derivatives. With this protocol, simultaneous exposures to the test compound and ^{3}H-thymidine were commenced at the end of a 1.5-hr attachment period and continued overnight; use of an automatic counter made measurement of UDS simpler and more precise. Repeat assays indicated that the noncarcinogens biphenyl and 2-aminobiphenyl did not elicit UDS, but the carcinogens 4-aminobiphenyl, dimethylaminobiphenyl, and p-diaminobiphenyl were positive. Carcinogen-induced UDS could also be measured by liquid scintillation counting as increased acid-precipitable counts, but the background was high. The background could be reduced by hydroxyurea, but the increase produced by dimethylaminobiphenyl remained proportionally the same. In HPC exposed to label only, the autoradiographic background was lowest in areas of the emulsion where no cells were present, and it was slightly higher over the cytoplasm than the nucleus. The finding of comparable backgrounds over the cytoplasm and nucleus was consistent with binding to macromolecules other than DNA. (15 refs)

78-2600 **Cytogenetic Effects of M-Phenylene Diamine (MPDA) and Methylene Dianiline (MDA) on Human Leukocytes In Vitro (Meeting Abstract).** (Eng) Ho, T. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Tipton, S. C.; Epler, J. L. *In Vitro* 14(4): 350; 1978. (no refs)

78-2601 **Effect of Mixed-Function Oxidase Modifiers on Metabolism and Toxicity of the Oncogen Dioxane.** (Eng) Woo, Y. T. (Seamen's Memorial Res. Lab., U.S. Public Health Service Hosp., New Orleans, LA, 70118); Argus, M. F.; Arcos, J. C. *Cancer Res* 38(6): 1621-1625; 1978.

The effect of inducers and inhibitors of hepatic mixed-function oxidases (MFO's) excretion of p-dioxane-2-one, the major urinary metabolite of dioxane, was studied. Pretreatment of male Sprague-Dawley rats with inducers such as phenobarbital (PB), polychlorinated biphenyls (PCB), and, to a much lesser extent, 3-methylcholanthrene (MC) increased metabolite excretion and shortened the time of onset of peak excretion. On the other hand, MFO inhibitors such as 2,4-dichloro-6-phenylphenoxyethylamine and cobaltous chloride decreased metabolite excretion. These findings implicate the involvement of MFO's in the in vivo metabolism of dioxane. p-Dioxane-2-one (0.5-1.2 g/kg) and dioxane (5.0-5.8 g/kg) were then injected ip into rats. The former was found to be considerably more toxic (LD$_{50}$ 0.79 g/kg, vs 5.3 g/kg for dioxane), suggesting that increased metabolism of the latter may bring about increased toxicity. The LD$_{50}$ of dioxane in PCB-, MC-, and PB-treated rats was 4.4, 5.2, and 5.4 g/kg, respectively. Thus, there was an apparent correlation between the metabolism and toxicity of dioxane in PCB- and MC-pretreated rats, but PB had no effect on the toxicity of the solvent. The lack of a PB effect may be due to the fact that p-dioxane-2-one is further metabolized to exert its toxic effect. Indeed, pretreatment of rats with PCB and MC further increased the toxicity of p-dioxane-2-one, but PB appeared to have the opposite effect. It is proposed that the generation of a toxic substance from dioxane involves a multistep mechanism with p-dioxane-2-one as an intermediate. (33 refs)

78-2602 **Carcinomas, Sarcomas and Other Lesions in Osborne-Mendel Rats Ingesting Endrin.** (Eng) Reuber, M. D. (NCI Frederick Cancer Res. Center, Frederick, MD, 21510). *Exp Cell Biol* 46(3): 129-145; 1978.

Osborne-Mendel male and female rats ingesting 0.1, 1.0, 5, 10, and 25 ppm endrin (1,2,3,4,10,10-hexachloro- 6,7-epoxy-1,4,4a,5,6,7,8,8a- octahydro- 1,4:5,8-endoendodimethanonaphthalene) developed malignant tumors in a variety of organs, as well as tumors of the liver, at a high incidence rate. The incidence of carcinomas and sarcomas was highest in male rats ingesting 0.1 ppm and in female rats ingesting 0.1 or 1.0 ppm endrin. The tumors were highly malignant and they included some rare and unusual types, such as Kupffer cell sarcomas of the liver and leiomyosarcomas of the mammary gland and stomach. Carcinomas or sarcomas were also present in the adrenal cortex, mammary gland, thyroid, uterus, lymph nodes, and other organs. In addition male rats developed an increased incidence of chronic renal disease. Tumors also developed, but at a lower rate, in male and female rats ingesting 1 ppm dieldrin. They included leiomyosarcoma of the parotid gland, adenocarcinoma of the lung, carcinoma of the pancreas, and hepatocellular carcinoma of the liver. Most of the carcinomas in the females were in the mammary gland. It is concluded that endrin is a carcinogen when given to Osborne-Mendel rats in the diet. (23 refs)

78-2603 **Novel Synthesis of the Dihydroarene Precursors of Carcinogenic Arene Dihydrodiols and Diolepoxides.** (Eng) Fu, P. P. (Ben May Lab. Cancer Res., Univ. Chicago, Chicago, IL, 60637); Lee, H. M.; Harvey, R. G. *Tetrahedron Lett* (6): 551-554; 1978.

A two-step procedure is reported for the synthesis of the dihydroarene precursors of carcinogenic arene dihydrodiols and diol epoxides directly from the parent hydrocarbons. The procedure involves regioselective hydrogenation over a platinum/carbon catalyst to the tetrahydroarene, followed by dehydrogenation with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone to the conjugated dihydroarene. (18 refs)

78-2604 **Cell and Microsome Mediated Binding of 7,12-Dimethylbenz(a)anthracene to DNA Studied by Fluorescence Spectroscopy.** (Eng) Ivanovic, V. (Inst. Cancer Res., Columbia Univ. Coll. Physicians and Surgeons, New York, NY, 10032); Geacintov, N. E.; Jeffrey, A. M.; Fu, P. P.; Harvey, R. G.; Weinstein, I. B. *Cancer Lett* 4(3): 131-140; 1978.

The fluorescence spectra of DNA isolated from hamster embryo cells incubated with 7,12-dimethylbenz(a)anthracene (DMBA) were compared with the spectra of DNA modified by DMBA or 7-hydroxymethyl-12-methylbenz(a)anthracene in a microsomal system and with the spectra of various model compounds. The spectra indicate that the 7-hydroxymethyl derivative bound to DNA in all cases and that it has a 9,10-dimethylanthracene-like chromophore. They also provide evidence of the similarity of the DNA-bound products of DMBA and its 7-hydroxymethyl derivative. The results are consistent with an activation mechanism that involves saturation of the 1,2,3,4-ring positions. (26 refs)

78-2605 **Evidence for the Involvement of a Diol-Epoxide in the Binding of 7,12-Dimethylbenz(a)anthracene to DNA in Cells in Culture.** (Eng) Dipple, A. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Nebzydoski, J. A. *Chem Biol Interact* 20(1): 17-26; 1978.

The binding of 7,12-dimethylbenz(a)anthracene (DMBA) to DNA was investigated in primary NIH Swiss mouse embryo cells cultured with 1,1,1-trichloropropene 2,3-oxide (TCPO), which inhibits epoxide hydrase. DMBA (0.07 μg/ml) was added to the culture medium, and the cells were harvested after 24 hr. TCPO inhibited the binding of DMBA to the murine cell DNA under conditions that did not appreciably decrease the overall metabolism of the carcinogen. This suggests that the formation of a trans-dihydrodiol is a necessary step in the metabolic pathway leading to DNA binding and that binding probably occurs through the generation of a reactive diol-epoxide. Chromatography of the DMBA-DNA product produced both in the presence and absence of TCPO suggests that two stereoisomeric diol-epoxides are involved in the binding of DMBA to DNA. (21 refs)

78-2606 **Differences Between Products of Binding of 7,12-Dimethylbenz(a)anthracene to DNA in a Target Tissue and in In Vitro Activating Systems (Meeting Abstract).** (Eng) Bigger, C. A. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Dipple, A. *Proc Am Assoc Cancer Res* 19: 162; 1978. (no refs)

78-2607 **Some Properties of Vicinal Diol-Epoxides Derived From Benz(a)Anthracene and Benzo(a)Pyrene.** (Eng) Phillips, D. H. (Chester Beatty Res. Inst., Fulham Rd., London SW3 6JB, England); Grover, P. L.; Sims, P. *Chem Biol Interact* 20(1): 63-75; 1978.

The alkylating properties of pairs of syn- and anti-isomers of two diol-epoxides derived from benzo(a)pyrene (BP) and of one derived from benz(a)anthracene (BA) were investigated. Of the anti-diol-epoxides, anti-BP 7,8-diol-9,10-oxide was the most reactive compound toward DNA, sodium p-nitrothiophenolate (in a nonaqueous solvent system), and 4-(p-nitrobenzyl)pyridine (in aqueous soln); anti-BP 9,10-diol-7,8-oxide was of intermediate reactivity and anti-BA 8,9-diol-10,11-oxide was the least reactive. The syn-diol-epoxides gave unsatisfactory results with DNA and 4-(p-nitrobenzyl)pyridine because of their rapid solvolysis in aqueous soln; with sodium p-nitrothiophenolate, their reactivity increased in the order syn-BP 7,8-diol-9,10-oxide > syn-BA 8,9-diol-10,11-oxide > syn-BP 9,10-diol-7,8-oxide. The products of the reaction between diol-epoxides and nucleic acids were examined by Sephadex LH-20 chromatography followed by high-pressure liquid chromatography (HPLC). The diol-epoxides reacted principally with the guanosine and adenosine moieties of RNA. (49 refs)

78-2608 **Cocarcinogenic and Irritant Factors of *Euphorbia Esula* L. Latex.** (Eng) Upadhyay, R. R. (Faculty Pharmacology, Dept. Pharmacognosy, Azarabadegan Univ., Tabriz, Iran); Bakhtavar, F.; Ghaisarzadeh, M.; Tilabi, J. *Tumori* 64(1): 99-102; 1978.

The latex of the plant *Euphorbia esula* contains the potent skin irritant ingenol-3-$\Delta^{2,4,6,8,10}$ pentene tetradecanoate and a cocarcinogen, ingenol-3-dodecanoate. The latter produced squamous cell papillomas when it was applied in a single dose with 7,12-dimethylbenz(a)anthracene to the back skin of NMRI mice. (15 refs)

78-2611 **The Structure of Tumours Derived from Mouse Submandibular Gland Epithelium Transformed In Vitro.** (Eng) Franks, L. M. (Dept. Cellular Pathology, Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Knowles, M. A. *Br J Cancer* 37(2): 240-247; 1978.

The morphology and ultrastructure of 48 primary tumors derived from 5 cell lines of adult mouse salivary gland epithelial cells transformed in vitro are described. Four of the tumor-producing cell lines developed after treatment of mice with 7,12-dimethylbenzanthracene, and one arose without carcinogen treatment. There were no significant differences between the tumors from the carcinogen-treated and untreated cell lines. Tumors from four of the cell lines were adenocarcinomas with a wide range of structural variation. The fifth cell line produced tumors with carcinomatous and sarcomatous elements. The morphology and ultrastructure of the tumors derived from the in vitro-transformed cells were almost identical to those of common human salivary gland tumors, particularly their more malignant variants. (12 refs)

78-2612 **The Metabolic Activation of 7-Methylbenz(a)anthracene in Mouse Skin: High Tumour-initiating Activity of the 3,4-Dihydrodiol.** (Eng) Chouroulinkov, I. (L'Institut de Recherches Scientifiques sur le Cancer, B.P. No. 8, 94800 Villejuif, France); Gentil, A.; Tierney, B.; Grover, P.; Sims, P. *Cancer Lett* 3(5/6): 247-253; 1977.

7-Methylbenz(a)anthracene (MBA) and its 1,2-, 3,4-, 5,6-, and 8,9-dihydrodiols were tested for their ability to initiate tumors following topical application to female CDI mice. The test compounds were applied as a single 25-μg dose; 1 wk after initiation, tumor formation was promoted with 12-O-tetradecanoylphorbol-13-acetate (TPA) three times a week. A dose of 0.5 μg TPA was used for the first 22 wk, 1 μg for the following 14 wk. The 3,4-dihydrodiol initiated the formation of more papillomas than MBA, and they arose at an earlier stage. The 1,2- and 5,6-diols were almost devoid of tumor-initiating activity. These findings support the suggestion that the metabolic activation of MBA involves the formation of a biologically active vicinal diol-epoxide, in this case 3,4-dihydro-3,4-dihydroxy-7-methylbenz(a)anthracene. (21 refs)

78-2613 **Changes in the Surface of Normal Rat Cells Cultured In Vitro after Single Exposure to 7,12-Dimethylbenz(a)anthracene.** (Rus) Belisheva, N. K. (Lab. Tumor Cell Genetics, Inst. Cytology, Leningrad, USSR); Fridlianskaia, I. I. *Tsitologiia* 20(3): 329-332; 1978.

Cells from normal rats were incubated 72 hr with 7,12-dimethylbenz(a)anthracene (DMBA: 0.1 and 0.5 μg/ml), and changes in the cell surface were determined by agglutination reactions with concanavalin A. Control cultures were incubated with dimethylsulfoxide. Incubation with 0.5 μg/ml DMBA considerably increased the agglutination of the cells considerably compared to control cells; this remained significant for 30 days, after which the DMBA-treated cells died. Incubation with 0.1 μg/ml also increased cell agglutination during the first days, but there was no significant difference between treated and control cells after 4 days. The long-term increase in the agglutinability of the cells treated with 0.5 μg/ml DMBA, cells in which mitosis was strongly inhibited, was due to the presence of DMBA in the cells. The short-term increase seen after the lower dose was due to dilution of the carcinogen as a result of mitosis. (13 refs)

78-2614 **Dibenz(a,c)anthracene: A Potent Inhibitor of Skin-Tumor Initiation by 7,12-Dimethylbenz(a)anthracene.** (Eng) Slaga, T. J. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Viaje, A.; Buty, S. G.; Bracken, W. M. *Res Commun Chem Pathol Pharmacol* 19(3): 477-483; 1978.

The mechanism by which the weak tumor initiator dibenz(a,c)anthracene [DB(a,c)A] inhibits the skin tumor-initiating activity of 7,12-dimethylbenz(a)anthracene (DMBA) was investigated in 7- to 9-wk-old female Charles River CD1 mice. DB(a,c)A [200 nanomoles (nmol)] was a potent inhibitor of DMBA skin tumor initiation when given either 5 min or 1, 12, or 36 hr before DMBA. Pretreatment of mice with 200 nmole unlabeled DB[a,c]A at either 1, 12, or 36 hr before killing increased the in vitro epidermally mediated covalent binding of ^{3}H-DMBA to DNA more than pretreatment with unlabeled DMBA at comparable times. In vitro covalent binding of ^{3}H-DMBA to DNA was substantially decreased when epidermal homogenates were isolated from mice pretreated with 200 nmole each of DMBA and DB(a,c)A rather than with DMBA only. The results suggest that some competition at the level of polycyclic hydrocarbon metabolism or at the genome level may exist between metabolites of the weak carcinogen and those of the strong carcinogen. (14 refs)

78-2615 **[^{3}H]Tamoxifen Binding Studies in Dimethylbenzanthracene-induced Mammary Carcinomata (Meeting Abstract).** (Eng) Nicholson, R. I. (Tenovus Inst. Cancer Res., Welsh Natl. Sch. Medicine, Heath Park, Cardiff CF4 4XX, Wales); Daniel, C. P.; Davies, P.; Griffiths, K. *J Endocrinol* 75(3): 26P-27P; 1977. (no refs)

78-2616 **Interaction of Androgens with Oestradiol-17β Receptor Proteins in DMBA-induced Mammary Tumours--A Possible Oncolytic Mechanism.** (Eng) Nicholson, R. I. (Tenovus Inst. Cancer Res., Welsh Natl. Sch. Medicine, Heath Park, Cardiff, CF4 4XX, Wales); Davies, P.; Griffiths, K. *Eur J Cancer* 14(4): 439-445; 1978.

The direct action of testosterone and other C_{19} steroids on the binding of ^{3}H-estradiol-17β to its receptor protein in both cytoplasmic and nuclear compartments was studied in Sprague-Dawley rats with mammary tumors induced by 7,12-dimethylbenz(a)anthracene (single dose of 20 mg via intubation). Androst-5-ene-3β,17β-diol and androstenediol were the most potent reducers of binding capacity, with substantial inhibition of ^{3}H-estradiol-17β binding being observed at concentrations as low as 25 nanomoles/liter. Compounds that did not compete with ^{3}H-estradiol-17β for cytoplasmic estradiol-17β binding sites were unable to instigate the nuclear translocation of the estrogen receptor. Androgen-transferred estrogen receptors had a relatively short nuclear retention time and readily bound ^{3}H-estradiol-17β at 4 C. It is suggested that the ability of compounds such as androstenediol to translocate the estrogen receptor to the nucleus may be the basis for the antitumor activity of androgens. (26 refs)

78-2617 **7,12-Dimethylbenz(a)anthracene-induced Alteration of Mammary Epithelial Cell RNA-Synthetic Patterns in Rat Strains of High and Low Tumor Incidence.** (Eng) DeAngelo, A. B. (Chemical Carcinogenesis, NCI-Frederick Cancer Res. Center, Frederick, MD 21701); Hudgins, W. R.; Kerby, S. B. *Cancer Res* 38(2): 384-389; 1978.

The influence of rat strain on 7,12-dimethylbenz(a)anthracene (DMBA)-induced alterations in the incorporation of [^{3}H]uridine into mammary epithelial cell RNA was studied using female Sprague-Dawley and Long-Evans rats. From 1 to 4 days after 20 mg DMBA was given intragastrically to 51-day-old Sprague-Dawley rats, a high tumor incidence strain, the specific activities of cytoplasmic and nucleolar RNA extracted from mammary gland epithelial cells decreased to 64 and 69% of the control value, respectively. This decrease was followed by a 40-100% stimulation of cellular RNA specific activity over control values throughout the remainder of the 28-day test period. In DMBA-treated Long-Evans rats, a low tumor incidence strain, the specific activity of RNA extracted from mammary epithelial cells did not differ from control values at any of the times studied with the exception of a smaller early time period decrease. DMBA did not alter the RNA specific activities in liver, kidney, duodenum, or mammary fibroblasts derived from either strain. Exposure of epithelial cells to DMBA (0.05 μg/ml) for 20 hr in vitro showed a similar early decrease of RNA specific activity in the Sprague-Dawley rats. The results suggest that RNA synthesis may be an early and distinguishable event characterizing tissues undergoing transformation. (23 refs.)

78-2618 **Polycyclic Aromatic Hydrocarbon (PAH) Metabolism in Normal and Neoplastic Human Breast Epithelial Cells in Culture (Meeting Abstract).** (Eng) Greiner, J. W. (Frederick Cancer Res. Center, Frederick, D, 21501); Janss, D. H.; Shepherd, R. E. *In Vitro* 14(4): 39-340; 1978. (no refs)

-2619 **Factors Affecting the Binding of Polycyclic Aromatic Hydrocarbons to Human Embryo ells, and Transformable and Non-Transformable Hamster mbryo Cells (Meeting Abstract).** (Eng) Raineri, R. (Chemi- l Carcinogenesis Section, Frederick Cancer Res. Center, rederick, MD, 21501); Poiley, J.; Hillesund, T. *In Vitro* 4(4): 337-338; 1978. (no refs)

-2620 **Biochemical Activation of Aryl Hydrocarbon Hydroxylase Activity, Cellular Distribution of olynuclear Hydrocarbon Metabolites, and DNA Damage Polynuclear Hydrocarbon Products in Human Cells In itro.** (Eng) Milo, G. E. (Dept. Veterinary Pathobiology, hio State Univ., 1900 Coffey Road, Columbus, OH, 43210); lakeslee, J.; Yohn, D.; DiPaolo, J. A. *Cancer Res* 38(6): 538-1644; 1978.

12-Dimethylbenzanthracene (DMBA), 3-methylcholanth- ne (3-MC), and benzo(a)pyrene (BP) were added to cul- res of human skin fibroblasts, and the sequence of events ading to transformation was studied. BP (at concentrations 10 μg/ml) induced mixed-function hydroxylase activity, tered cell proliferation kinetics, and caused DNA damage, measured by altered grain count and bromodeoxyuridine corporation. 3-MC, at concentrations as high as 15 μg/ml, as ineffective. DMBA, at concentrations ≥6 μg/ml, in- uced mixed-function oxygenase and stimulated DNA syn- esis and cell proliferation, but caused little or no cytotoxici- or DNA damage at these concentrations. The oncarcinogenic analogs 6,8,12-trimethylbenzanthracene, -fluorodimethylbenzanthracene, anthracene, and phenanth- ne had no detectable effect on the human cells. These re- ılts indicate that BP is highly suspect as a direct carcinogen cocarcinogen for human cells. (32 refs)

8-2621 **Separation of Glutathione S-Transferase Activities with Expoxides from the Mouse Liver -Protein, a Major Polycyclic Hydrocarbon-Binding rotein.** (Eng) Sarrif, A. M. (Dept. Pharmacology and omprehensive Cancer Center, Univ. Alabama in irmingham Medical Center, Univ. Station, Birming- am, AL, 35294); McCarthy, K. L.; Nesnow, S.; Heidel- erger, C. *Cancer Res* 38(5): 1438-1443; 1978.

he relationship between the *h*-protein and enzymes of iouse liver was studied in C3H mice. Carboxymethylcel- ulose and isoelectrofocusing columns allowed the separation f *h*-protein from glutathione S-transferase activities with 1,2-epoxy-(3-p-nitrophenoxy)propane and benz(a)anthracene-5,6-oxide as substrates. It was also possible to purify the *h*-protein as a ^{3}H-7,12-dimethylbenz(a)anthracene conjugate and in its free form. These findings do not suggest an involvement of the *h*-protein in hydrocarbon carcinogen detoxification. (27 refs)

78-2622 **Plant Metabolic Activation of 1,2-Dibromoethane (EDB) to a Mutagen of Greater Potency.** (Eng) Scott, B. R. (Science Park, Res. Div., Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., P.O. Box 418, Smithville, TX, 78957); Sparrow, A. H.; Schwemmer, S. S.; Schairer, L. A. *Mutat Res* 49(2): 203-212; 1978.

An investigation was conducted to confirm the mutagenicity of 1,2-dibromoethane (DBE) in liquid tests and to determine whether the addition of plant mixtures to the microbial cultures would elevate the levels of mutagenicity detected. The plant extract consisted of cuttings from the Tradescantia hybrid clone 4430 that had been dried, ground into powder, and centrifuged. With both *Aspergillus nidulans* and *Escherichia coli* WP2 try-, inactivation and induction of mutation due to DBE were higher in the presence of the plant extract than in its absence. This effect was not due to a synergistic effect between the mutagen and the plant mix, because with ethyl methanesulfonate, the degree of mutagenicity and inactivation was depressed in the presence of the plant extract. The increase in the mutagenicity of DBE was energy-dependent, because omission of NADPH from the treatment mixture abrogated the effect. With *E. coli*, residual DBE exhibited a greater effect than the DBE distillate for inducing both inactivation and reversion to tryptophan independence. In the presence of the plant mix, however, elevated biological end-point values were observed for both fractions. The plant mix alone exerted no significant effect on inactivation. Apparently, DBE can be converted into a mutagen either by a pathway involving a breakdown product in vitro or by a pathway involving metabolic activation by plants. (31 refs)

78-2623 **Carcinogenesis in Rats of Combined Ethylene Dibromide and Disulfiram (Letter to Editor).** (Eng) Plotnick, H. B. (Natl. Inst. Occupational Safety and Health, Cincinnati, OH). *JAMA* 239(16): 1609; 1978.

Administration of ethylene dibromide (20 ppm, by inhalation) plus disulfiram (0.05% by wt, in diet) to Sprague-Dawley rats increased morbidity, mortality, and tumor formation. Hemangiosarcomas of the liver, spleen, omentum, and kidney were noted in both sexes; adenocarcinomas of the mammary gland were noted in females; and tubular atrophy of the testes was noted in males. It is not known if this industrial chemical-drug interaction is of clinical significance in humans. (no refs)

78-2624 **Induction of Respiratory Deficient Mutants in *Saccharomyces cerevisiae* by Mono- and Diazido Analogs of Ethidium.** (Eng) Morita, T. (Lab. Molecular Biology, Univ. Alabama, University Station, Birmingham, AL, 35294); Yielding, K. L. *Mutat Res* 56(1): 21-30; 1977.

The ability of ethidium bromide (EB), ethidium monoazide (EA_1), and ethidium diazide (EA_2) to induce respiratory-deficient (RD) mutants in *Saccharomyces cerevisiae* was compared under dark conditions and with photolysis in situ. EA_1 and EA_2 did not induce RD mutants in the dark at concentrations up to 6 μM, but they induced more than 90% RD mutants in the light at concentrations of 2 and 6 μM, respectively. The highest proportion of RD mutants for EA_1 and EA_2 was seen after 30 and 10 min exposure in the light, respectively. EB competed with either EA_1 or EA_2 for RD induction when applied before, but not after, the photolysis step, suggesting that the initial mutagenic binding sites for the azides are identical with those of EB. There was no self-rescue or recovery in azide mutagenesis as there is with EB, and recovery from azide mutagenesis could not be provoked by EB. Thus, a simple competition between the binding of EB and its azide analogs accounts for the prevention by EB of the azide-induced mutations. (17 refs)

78-2625 **Sister Chromatid Exchanges in Human Lymphoid Cell Lines Cultured in Diffusion Chambers in Mice.** (Eng) Huang, C. C. (Dept. Experimental Biology, Roswell Park Memorial Inst., Buffalo, NY, 14263); Furukawa, M. *Exp Cell Res* 111(2): 458-461; 1978.

A host-mediated assay system for evaluating the mutagenic potential of a compound was developed. It involves culturing cells from human lymphoid lines in diffusion chambers that are subsequently implanted into mice. The system was tested using two cell lines, B35M, a Burkitt's lymphoma line, and Jeff, a line derived from a normal individual. One day after implantation of the diffusion chambers, the hosts received 12 hourly ip injections of 5-bromodeoxyuridine (BUdR; 0.5 x 10^{-2} M). A single ip injection of cyclophosphamide at 7.5, 15, or 30 μg/g was given 13 hr after the first injection of BUdR, and the diffusion chambers were harvested 30-36 hr after the first BUdR injection. Chromosome preparations were examined for metaphases with differentially stained chromatids, and the number of sister chromatid exchanges (SCE)/metaphase was enumerated. The number of SCE/cell in all the cyclophosphamide-treated diffusion chambers was significantly higher than that in controls and was dose-dependent. The Burkitt cell line seemed to be more sensitive to cyclophosphamide treatment than the normal line. This host-mediated assay system may be useful for screening certain classes of mutagens or carcinogens. However, simplification of the procedure is needed, especially the BUdR administration. (17 refs.)

78-2626 **Association Between Chloroform Levels in Finished Drinking Water Supplies and Various Site-Specific Cancer Mortality Rates (Meeting Abstract).** (Eng) Hogan, M. D. (Biometry Branch, NIEHS, Research Triangle Park, NC, 27709); Chi, P.; Mitchell, T. J.; Hoel, D. G. *Environ Health Perspect* 20: 247-248; 1977. (no refs)

78-2627 **Dominant Lethal Studies with the Halogenated Olefins Vinyl Chloride and Vinylidene Dichloride in Male CD-1 Mice.** (Eng) Anderson, D. (Central Toxicology Lab., Imperial Chemical Industries, Ltd., Alderley Park nr. Macclesfield, Cheshire SKIO 4TJ, England); Hodge, M. C.; Purchase, I. F. *Environ Health Perspect* 21: 71-78; 1977.

Vinyl chloride (VC) and vinylidene dichloride (VDC) were assessed by the dominant lethal test for mutagenic activity in fertile male CD-1 mice. Compared with control males exposed to air, VC and VDC did not cause dominant lethal mutations at 3,000, 10,000, and 30,000 ppm and at 10, 30, and 50 ppm, respectively. (17 refs)

78-2628 **Report on Bioassay of 1,1-Dichloroethane for Possible Carcinogenicity.** (Eng) Fredrickson, D. S. (NIH, Bethesda, MD, 20014). *Fed Register* 43(143): 32190-32191; 1978.

1,1-Dichloroethane was administered by gavage to male and female Osborne-Mendel rats (382-950 mg/kg/day) and B6C3F1 mice (1,442-3,331 mg/kg/day) 5 days/wk for 78 wk. Rats were sacrificed 33 wk later, mice 13 wk later. Survival rates were poor in all rats and in several mouse groups. There were dose-related marginal increases in adenocarcinomas and in hemangiosarcomas among female rats and there was a statistically significant increase in the incidence of endometrial stomal polyps among female mice. (no refs)

78-2629 **The Mutagenic Effect of 1,2-Dichloroethane on *Salmonella Typhimurium* I. Activatio Through Conjugation with Glutathione In Vitro.** (Eng Rannug, U. (Environmental Toxicology Unit, Univ Stockholm, S-106 91 Stockholm, Sweden); Sundvall

A.; Ramel, C. *Chem Biol Interact* 20(1): 1-16; 1978.

The weak mutagenicity of 1,2-dichloroethane (1,2-DE) for *Salmonella typhimurium* TA1535 was increased by the addition of a metabolizing system, ie, the S-9 postmitochondrial rat liver fraction. This activation was further increased by the addition of reduced glutathione (GSH). No activation occurred when GSH was added in the presence of a totally denatured S-9 fraction or in the absence of this fraction. Glutathione S-transferases A and C significantly increased the mutagenicity of 1,2-DE in the presence of GSH. A synthetic conjugate, S-(2-chloroethyl)-L-cysteine, gave a strong direct mutagenic effect at 0.2-5.0 μmol/plate, concentrations at which no effects were seen with 1,2-DE. Thus, it is concluded that 1,2-DE is activated by conjugation to GSH. (24 refs)

78-2632 **Inhalation Toxicity of Vinyl Chloride and Vinylidene Chloride.** (Eng) Lee, C. C. (Pharmacology and Toxicology, Midwest Res. Inst., 425 Volker Blvd., Kansas City, MO, 64110); Bhandari, J. C.; Winston, J. M.; House, W. B.; Peters, P. J.; Dixon, R. L.; Woods, J. S. *Environ Health Perspect* 21: 25-32; 1977.

Experiments on the inhalation toxicity and carcinogenicity of vinyl chloride (VC) and vinylidene chloride (VDC) in mice and rats are reported. The exposure of mice to 1,000 ppm VC for 6 hr/day, 5 days/wk caused some acute deaths with toxic hepatitis and marked tubular necrosis of the renal cortex. During the sixth month, mice exposed to 1,000, 250, or 50 ppm VC became lethargic, lost weight quickly, and died; only a few mice exposed to 50 ppm survived for 12 mo. In mice exposed to 50, 250, or 1,000 ppm VC, there was a high incidence of bronchioloalveolar adenoma, mammary gland tumors (including ductular adenocarcinoma), squamous and anaplastic cell carcinomas with metastasis to the lung, and hemangiosarcoma (HS) in the liver and, to a lesser extent, in other organs. The incidence and severity of these tumors were proportional to the levels and duration of exposure. Malignant lymphoma involving various organs was observed in a few mice. Rats were more resistant to the toxic effects of VC, and exposure to 1,000 ppm slightly depressed the body wt of females. Exposures of 250 and 1,000 ppm VC caused a number of deaths and hepatic HS during the 9th mo. Most rats with hepatic HS also developed HS in the lung. HS occasionally occurred in other tissues, including omentum, mesentery, or sc tissue, of rats exposed to 50, 250, or 1,000 ppm VC. The exposure of mice to 55 ppm VDC also caused a few acute deaths and a few hepatic HS. Inflammatory, degenerative, and mitotic changes occurred in the liver. No mouse exposed to VDC developed any mammary gland tumors. Several mice had a bronchioloalveolar adenoma. The exposure of rats to 55 ppm VDC slightly depressed body wt; HS occurred in the mesenteric lymph node or sc tissue of two rats. (25 refs)

78-2633 **Formation of $3,N^4$-Ethenocytidine Moieties in RNA by Vinyl Chloride Metabolites In Vitro and In Vivo.** (Eng) Laib, R. J. (Institut fur Toxikologie, Universitat Tubingen, Wilhelmstrasse 56, D-7400 Tubingen, W. Germany); Bolt, H. M. *Arch Toxicol (Berl)* 39(3): 235-240; 1978.

Rats were exposed to ^{14}C-vinyl chloride, and the in vivo liver metabolites were examined. In addition to RNA and $1,N^6$-ethenoadenosine, $3,N^4$-ethenocytidine was also radioactively labeled. In vitro experiments using vinyl chloride-exposed liver microsomes and NADPH produced the same results. These alkylation mechanisms are consistent with the mutagenic and carcinogenic properties of vinyl chloride. (22 refs)

78-2634 Disposition and Metabolism of [^{14}C]1,1-Di**chloroethylene after Single Oral Administration in Rats (Meeting Abstract).** (Eng) Reichert, D. (Dept. Toxicology, Univ. Wurzburg, Versbacher Landstrasse 9, D-8700 Wurzburg, W. Germany); Werner, H. W. *Naunyn Schmiedebergs Arch Pharmacol* 302(Suppl): R22; 1978. (1 ref)

78-2635 **1,1-Dichloroethylene Hepatotoxicity: Proposed Mechanism of Action and Distribution and Binding of ^{14}C Radioactivity Following Inhalation Exposure in Rats.** (Eng) Jaeger, R. J. (Toxicology Unit, Dept. Physiology, Kresge Center Environmental Health, Harvard Sch. Public Health, 665 Huntington Ave., Boston, MA, 02115); Shoner, L. G.; Coffman, L. *Environ Health Perspect* 21: 113-119; 1977.

The mechanism of 1,1-dichloroethylene (1,1-DCE)-induced hepatotoxicity and its potentiation by fasting were determined in male Holtzman rats, and results on tissue distribution and binding of radioactivity (RA) were related to the proposed mechanism of action. Trichloropropane epoxide (TCPE: 0.1 ml/kg po), an epoxide hydrase inhibitor, significantly increased the toxicity of 1,1-DCE (100-150 ppm by inhalation, x 4 hr) in 18-hr-fasted (FA) rats, as measured by serum sorbitol dehydrogenase (SDH) elevation. When FA rats were exposed to 250 ppm 1,1-DCE alone, hepatic citric acid levels were increased 416%, SDH activity 636.4-fold (vs increases of 122% and 100-fold in fed [FE] rats). It was hypothesized that mitochondrial injury was associated with inhibition of the tricarboxylic acid cycle and that monochloroacetic acid is the toxic metabolite of 1,1-DCE. When FE and FA rats were exposed for 2 hr to 2,000 ppm ^{14}C-1,1-DCE in a recirculating exposure chamber, there was no difference in rate of uptake between the two groups. FA rats had more water- or trichloroacetic acid (TCA)-soluble 1,1-DCE metabolites in their tissues than FE rats. At 30 min postexposure, most of the total RA (mainly TCA-soluble) was detected in the kidneys of both groups. FA rats had more tissue-bound or TCA-insoluble RA in their mitochondrial and microsomal fractions than FE rats, but both groups had approx the same rate of disappearance of RA (half-time of 2-3 hr). At 26 hr, the urinary excretion of RA was similar in FE and FA rats (36.6%). The results suggest that although there are no significant metabolic differences between FE and FA rats, there does appear to be a significant difference in the in vivo pathway for the products of metabolism. The fact that mice develop renal tumors after long-term 1,1-DCE exposure but rats only show significant hepatocellular injury is explained. (27 refs)

78-2636 **The Biological Fate of Vinylidene Chloride in Rats.** (Eng) Jones, B. K. (Central Toxicology Lab., Imperial Chemical Industries, Ltd., Alderley Park, Cheshire SK10 4TJ, England); Hathway, D. E. *Chem Biol Interact* 20(1): 27-41; 1978.

The fate of vinylidene chloride (DCE) following intragastric (ig), iv, or ip administration to male Alderley Park rats was determined. In rats given 500-μg/kg or 350-mg/kg doses of labeled DCE by all three routes, almost all the radioactivity was recovered within 72 hr of dosing; with 500 μg/kg ig, however, small amounts of label were still being recovered 72-108 hr after dosing. With the higher ig dose, nearly 70% of the dose was excreted as unchanged DCE and 1% as DCE-related CO_2 by the lungs; with the lower dose, urinary excretion accounted for 80%, and $<1\%$ of the unchanged DCE plus 4%-6% of DCE-CO_2 were eliminated by the lungs. This change in excretion pattern appeared to be due to a saturable drug metabolism and an arterial-alveolar transfer of unchanged DCE from the blood. In comparison, 80% of the small iv dose was excreted unchanged from the blood within 1 hr ($>60\%$ within 5 min). The excretion pattern after a small ip dose was intermediate between that resulting from iv and that from ig administration. For groups of rats administered various dose levels ig within a 1,300-fold dose range, the plot of the pulmonary excretion of unchanged DCE against the log of the reciprocal doses was biphasic. Radiography following ig doses revealed the presence of large amounts of the ^{14}C label in the kidneys and liver after 30 min and a more general distribution of ^{14}C throughout the soft organs at 1 hr. The kidneys and liver retained the label for the longest times. Biotransformation resulted in thiodiglycollic acid and an N-acetyl-S-cysteinylacetyl derivative as the major urinary metabolites, together with substantial amounts of chloroacetic acid, dithioglycollic acid, and thioglycollic acid. (12 refs)

78-2637 **Carcinogenicity Studies on Vinylidene Chloride.** (Eng) Viola, P. L. (Regina Elena Inst. Cancer Res., Rome, Italy); Caputo, A. *Environ Health Perspect* 21: 45-47; 1978.

The possible carcinogenicity of vinylidene chloride (VDC) was determined in two experiments, one using Wistar rats, one using Sprague-Dawley rats. The Wistar rats inhaled VDC for 4 hr/day, 5 days/wk, for 12 mo at a concentration of 200 ppm for 5 mo, 100 ppm thereafter. The animals were allowed to die spontaneously (life-span was 22-24 mo). Tumors, all occurring in the abdominal cavity except for one in the liver and one in the lung, were found in 8/51 males and 9/23 females. The diagnosis was reticulum cell sarcomas of a nonsyncytial type. However, many abdominal tumors were also found in control rats (5/30 males, 10/30 females). This prompted the second experiment, in which Sprague-Dawley rats were exposed to 75 or 100 ppm. Tumor incidence in the controls was practically identical to that found in the 100 ppm group and higher than that in the 75 ppm group. Microscopic examination of the tissues and organs from all animals is incomplete. Nevertheless, it seems clear that there is no grossly observable correlation between tumor formation and VDC inhalation. (7 refs)

78-2638 **Metabolism of Trichloroethylene and Tetrachloroethylene in Human Subjects.** (Eng) Ikeda, M. (Dept. Environmental Health, Tohoku Univ. Sch. Medicine, Sendai 980, Japan). *Environ Health Perspect* 21: 239-245; 1977.

The metabolism of trichloroethylene (3C-E) and tetrachloroethylene, (4C-E) in humans and the urinary concentration of metabolites of these compounds in persons occupationally exposed to their vapors was determined. There was a linear correlation between 3C-E concentration in the work environments and the level of total trichloro compounds in the urine of workers. The trichloroethanol level was also linearly related to 3C-E concentration, but trichloroacetic acid levels deviated from linearity at 3C-E levels > 50 ppm. With 4C-E, the trichloroethanol, trichloroacetic acid, and total trichloro compound levels all plateaued at 4C-E levels < 100 ppm. The respiratory and urinary half lives of 3C-E were 25 and 42 hr, respectively, but those of 4C-E were 65 and 144 hr, respectively. Urinalysis of a 38-yr-old man addicted to 3C-E revealed a urinary half-life of > 70 hr. An automated system for the determination of total trichloro compounds in human urine is described. (35 refs)

78-2639 **Transforming Activities of Trichloroethylene and Proposed Industrial Alternatives.** (Eng) Price, P. J. (Microbiological Associates, Torrey Pines Res. Center, 2945 Science Park Road, La Jolla, CA, 92037); Hassett, C. M.; Mansfield, J. I. *In Vitro* 14(3): 290-293; 1978.

The carcinogenicity of trichloroethylene (TCE) and three industrial substitutes, 1,1,1-trichloroethane, tetrachloroethylene, and methylene chloride, was tested in vitro using the F1706 Fischer rat embryo cell system. All compounds induced transformation in the rat cells. Toxicity studies indicated that TCE was the least toxic of the four compounds by a factor of at least 100. Sc injection of transformed cells into newborn Fischer rats resulted in undifferentiated fibrosarcomas at the injection site in 100% of the animals in 27-68 days. (4 refs)

78-2640 **Carcinogenicity Studies on Halogenated Hydrocarbons.** (Eng) Weisburger, E. K. (Carcinogen Metabolism and Toxicology Branch, NCI, NIH, Bethesda, MD, 20014). *Environ Health Perspect* 21: 7-16; 1977.

The acute and chronic carcinogenicities of a series of halogenated hydrocarbons were studied in Osborne-Mendel rats and B6C3F1 mice. The test chemical was given by gavage 5 days/wk for 6 wk (acute studies) or 78 wk (chronic studies). Trichloroethylene had little effect on rats but caused hepatocellular carcinomas (HC) in mice. Chloroform caused HC in mice, kidney tumors in male rats, and thyroid tumors in female rats. 1,1,1-Trichloroethane had no effect on either species, whereas iodoform produced a slight increase in thyroid tumors in male rats. 1,2-Dibromoethane and 1,2-dibromo-3-chloropropane (DBCP) caused squamous cell carcinomas of the stomach with metastases in both species: DBCP also caused mammary tumors in female rats. 1,2-Dichlorethane produced some stomach tumors in male rats, HC in male mice, and lung tumors in males and females of both species. 1,1-Dichloroethane had little effect on rats, but caused a slight increase in HC in male mice. 1,1,2-Trichloroethane and hexachloroethane also had little effect on rats but increased the number of HC in mice, whereas 3-chloropropene decreased the hepatomagenic effect in mice. Tetrachloroethylene increased the number of HC in mice but had no effect in rats. Carbon tetrachloride, used as a positive control, produced HC in rats and mice as well as thyroid tumors in mice. The results suggest that po administration of many halogenated aliphatics might pose a carcinogenic hazard to humans on continued exposure. (9 refs)

78-2641 **Elevated CEA Levels in a Group of Polyvinyl Chloride Workers.** (Fre) Page, M. (Service de Recherche et de Biochimie, Hotel-Dieu de Quebec, Quebec, Canada); Theriault, L.; Delorme, F. *Ann Immunol (Paris)* 128 C(6): 1101-1103; 1977.

Plasma levels of carcinoembryonic antigen (CEA) were assayed in 200 polyvinyl chloride (PVC) workers and compared to levels in a normal population of 10,000 subjects that included smokers and nonsmokers. The results for the PVC workers were tabulated according to length of time in the industry and type of work performed. Elevated CEA levels (above 5 nanograms/ml) were found in 56% of the workers but only 9.2% of the nonworkers. It is concluded that screening PVC workers for elevated CEA levels could detect benign or malignant hepatic lesions. (8 refs.)

78-2642 **Effects of the Epoxide Hydrase Inhibitor, 1,1,1-Trichloropropane-2,3-oxide on the Genetic Activity of Aflatoxin B_1 Metabolites in In Vitro Activation Test Systems.** (Eng) Callen, D. F. (Environmental Mutagenesis Branch, Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC, 27709); Ong, T. M. *Mutat Res* 49(3): 371-376; 1978.

Studies were conducted to determine if the epoxide hydrase inhibitor 1,1,1-trichloropropane 2,3-oxide (TCPO) is genetically active and if its addition to an in vitro activation system would alter the genetic activity of aflatoxin B_1 (AFB_1) to either *Neurospora crassa* or *Saccharomyces cerevisiae*. TCPO was genetically active to cells of *S. cerevisiae* and conidia of *N. crassa*. The genetic activity could be eliminated by addition of the supernatant fraction of hamster liver homogenate (S-9) to the treatment soln. This can be explained by the rapid binding of TCPO to epoxide hydrase and other proteins within the S-9 fraction, which results in a partial or complete absence of unbound TCPO able to penetrate the indicator cell and bind to DNA. The addition of TCPO to an in vitro activation system containing AFB_1 resulted in an increase in the genetic activity of AFB_1 that was dependent on the TCPO dose. This effect can be interpreted as genetic evidence for the proposal that AFB_1 is metabolized to aflatoxin B_1 2,3-oxide, which can be further metabolized by epoxide hydrase to a dihydrodiol that is not genetically active. The inhibition of epoxide hydrase activity by TCPO results in an increase in the availability of AFB 2,3-oxide to interact with DNA, which is reflected in the increased AFB mutagenicity. Alternatively, competition between TCPO, which is itself genetically active, and the active metabolite of AFB$_1$ within the S-9 fraction could also result in an increase in mutagenicity. (12 refs)

78-2643 **Alkylating and Mutagenic Effects of Allyl and Allylogenic Compounds (Meeting Abstract).** (Eng) Eder, E. (Dept. Toxicology, Univ. Wurzburg, Versbacher Landstrasse 9, D-8700 Wurzburg, W. Germany); Neudecker, T. *Naunyn Schmiedebergs Arch Pharmacol* 302(Suppl): R21; 1978. (1 ref)

78-2644 **Effect of Carbon Tetrachloride on Carcinogenicity of *Petasites japonicus* and Transplantability of Induced Tumors.** (Eng) Mori, H. (Dept. Pathology, Gifu Univ. Sch. Medicine, 40 Tsukasamachi, Gifu 500, Japan); Ushimaru, Y.; Tanaka, T.; Hirono, I. *Gann* 68(6): 841-845; 1977.

The effect of carbon tetrachloride on the carcinogenicity of the flower stalk of *Petasites japonicus* was examined in three groups of inbred ACI rats. Group 1 received a 4% petasites diet and CCl$_4$ (intragastrically, once every 2 wk) over a 30-wk period. Group 2 received only the 4% petasites diet and Group 3 received CCl$_4$ and a basal diet. Both Groups 1 and 2 showed the same incidence of hemangioendothelial sarcoma of the liver (6/22). However, the incidence of hyperplastic liver nodules (19/22) and liver cell adenomas (8/22) in Group 1 was significantly higher than that in Group 2 (2/22, 0/22). No hyperplastic liver nodules or liver cell adenomas were noted in Group 3. These results indicate that CCl$_4$ probably enhanced the carcinogenic activity of *Petasites japonicus* in hepatocellular tumorigenesis. Three hepatic hemangioendothelial sarcomas induced in rats of Groups 1 and 2 were transplanted sc and established as transplantable lines. (7 refs)

78-2645 **Chronic Toxicity and Reproduction Studies of Hexachlorobutadiene in Rats.** (Eng) Kociba, R. J. (Toxicology Res. Lab., Health and Environmental Res., Dow Chemical Co., Midland, MI, 48640); Schwetz, B. A.; Keyes, D. G.; Jersey, G. C.; Ballard, J. J.; Dittenber, D. A.; Quast, J. F.; Wade, C. E.; Humiston, C. G. *Environ Health Perspect* 21: 49-53; 1977.

The carcinogenic, reproductive, and toxic effects of po hexachlorobutadiene (HCBD), an unwanted by-product of processes associated with the chlorination of hydrocarbons, were assessed in Sprague Dawley rats. The LD$_{50}$ values following a single po dose ranged from 504 to 667 mg/kg in adult male rats and from 200 to 400 mg/kg in adult female rats. In 21-day-old male and female weanling rats, the LD$_{50}$ values were 46-91 and 26-81 mg/kg, respectively. In a chronic toxicity study, the ingestion of 20 mg/kg/day HCBD for up to 2 yr caused multiple toxicologic effects, primarily of the kidney. These included the development of renal tubular adenomas and adenocarcinomas. The ingestion of 2 mg/kg/day HCBD caused lesser toxicity and no evidence of neoplasia. No toxic effects were observed in rats chronically exposed to a po dose of 0.2 mg/kg/day. Thus, a dose-response relationship was observed for HCBD-induced toxicity,which affected primarily the kidney; HCBD-induced neoplasms occurred only at a dose level higher than that causing discernible renal injury. In a reproduction study, 20 or 2.0 mg/kg/day HCBD induced slight maternal toxicity (primarily of the kidney), but caused no adverse effects on reproductive parameters (percent pregnancy and neonatal survival/development). A decreased neonatal body wt was noted at 20 mg/kg/day. No toxicologic effects were observed among adult rats at 0.2 mg/kg/day or among neonates at 0.2 or 2.0 mg/kg/day. (14 refs)

78-2646 **The Gas Chromatographic Analysis of Bis(chloromethyl) Ether in Air.** (Eng) Baba, Y. (Natl. Res. Inst. Pollution and Resources, Kawaguchi, Saitama 332, Japan); Tanaka, T. *Bull Chem Soc Jpn* 51(1): 317-318; 1978.

A gas chromatographic method for the determinatior of bis(chloromethyl) ether (BCME) concentration was devised. BCME was converted into bis(ethylthio methyl) ether by reaction with sodium ethanethiolat in the hexane soln. The sulfur-containing derivativ was then detected using a flame photometric detector This method allows BCME determination in sample of air containing BCME and other compounds. (refs)

78-2647 **Study of the Mutagenic Potential of Bis(2 chloroethyl) and Bis(2-chloroisopropyl Ethers in Mice by the Heritable Translocation Tes (Meeting Abstract).** (Eng) Jorgenson, T. A. (Stanfor Res. Inst., Menlo Park, CA); Rushbrook, C. J.; Newell G. W.; Tardiff, R. G. *Mutat Res* 53(1): 124; 1978 (no refs)

78-2648 **Butyric Acid Suppression of the In Vitro Neoplastic State of Syrian Hamster Cells.** (Eng Leavitt, J. (Dept. Biochemistry, Johns Hopkins Univ., Sch Hygiene and Public Health, Baltimore, MD 21205); Barrett J. C.; Crawford, B. D.; Ts'o, P. O. *Nature* 271(5642): 262-265 1978.

The effects of butyric acid on altered growth properties associated with the neoplastic state were examined in a highl tumorigenic Syrian hamster fibroblast cell line, BP6T, anc two clonal isolates, BP6T-But 1 and BP6T-But 2 (isolated from BP6T cells grown in the presence of 2 mM butyric acid). The addition of 2 mM butyric acid to the growth medium decreased the doubling time by 4-7 hr and reduced the cell saturation density by 20%-70% in all three cell lines. Cloning efficiencies ranged from 14% to 25% in medium containing butyric acid and 65-85% in normal medium. In contrast to the slight effect on general growth, butyric acid produced marked effects on colony morphology, anchorage-dependent growth, and fibrinolytic activity of BP6T cells. All colonies displayed morphologies similar to those of BP6T-But 1 and BP6T-But 2; ie, they were oriented in a uniform, parallel pattern within the colony, a pattern similar to that of untransformed Syrian hamster cells. In the presence of butyric acid, none of the cell lines was able to form colonies in semisolid agar, compared to a 50% cloning efficiency without butyric acid. BP6T-But 1 and BP6T-But 2 cells grown in the presence of butyric acid produced levels of extracellular fibrinolytic activity that were 85%-95% lower than those of BP6T cells grown in the absence of butyric acid. BP6T and BP6T-But 1 cells grown in the presence of butyric acid (the former for 48 hr, the latter for 14 passages) had a 70%-90% reduction in intracellular fibrinolytic activity. All of these effects were reversible. It is suggested that this system could be of value in investigations of the cellular control mechanism of neoplasia. (21 refs.)

78-2649 **A Linear Relationship Between Tumorigenic Potency In Vivo and Mutagenic Potency at the Heterozygous Thymidine Kinase (TK$^{+/-}$) Locus of L5178Y Mouse Lymphoma Cells Coupled with Mammalian Metabolism (Meeting Abstract).** (Eng) Clive, D. (Genetic Toxicology Lab., Burroughs Wellcome Co., Research Triangle Park, NC). *Mutat Res* 53(1): 95; 1978. (no refs)

78-2650 **Loss of Activity of an N'-Methyl-4-pyridone-5-carboxamide-forming N'-Methylnicotinamide Oxidase in Livers of Rats Fed 2-Acetylaminofluorene.** (Eng) Ohkubo, M. (Div. Biochemistry, Chiba Cancer Center Res. Inst., Nitona-cho 666-2, Chiba 280, Japan); Fujimura, S. *Cancer Res* 38(3): 697-702; 1978.

N^{1}-Methylnicotinamide oxidase (MNO) activity was compared in the livers of control and 2-acetylaminofluorene (2-AAF)-treated Wistar rats. In the liver homogenates from the 39-wk-old controls, three enzyme fractions were eluted by diethylaminoethyl cellulose column chromatography. Fraction I produced 1-methyl-2-pyridone-5-carboxamide (2-PY) and was identified as xanthine oxidase. Fraction II formed 2-PY (72%) in preference to 1-methyl-4-pyridone-5-carboxamide (37%), but Fraction III produced only 4-PY. The 4-PT- and 2-PY-forming activity of Fraction II (MNO-I) increased with an increase in pH, but the activity of Fraction III (MNO-II) was max at pH 8.5. In the liver homogenate of a rat fed a diet containing 0.05% 2-AAF for 24 wk (beginning at age 6 wk), followed by a normal diet for 9 wk, MNO activities were observed only in Fractions I and II. MNO-II activity was lacking, but the elution character of Fractions I and II was similar to that of the corresponding fractions from the control liver. In Fraction II from control or 2-AAF-treated liver, the Km's for the MNO of 2-PY and 4-PY formation were in the same range. In the control liver, the Km for the MNO of 4-PY formation was one-fifth of that of the Fraction II enzymes. (13 refs.)

78-2651 **A Glycolipid Cascade in Experimental Liver Tumorigenesis (Meeting Abstract).** (Eng) Morre, D. J. (Purdue Univ., West Lafayette, IN, 47907); Merritt, W. D.; Richardson, C. L.; Kloppel, T. M.; Keenan, T. W. *Fed Proc* 37(6): 1767; 1978. (no refs)

78-2652 **Alteration of the Ability of Liver Microsomes to Activate N-2-Fluorenylacetamide to a Mutagen of *Salmonella typhimurium* During Hepatocarcinogenesis.** (Eng) Stout, D. L. (Dept. Anatomic and Res. Pathology, M. D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Becker, F. F. *Cancer Res* 38(8): 2274-2278; 1978.

Male Sprague-Dawley rats were exposed to a hepatocarcinogenic regimen of N-2-fluorenylacetamide (FAA: 0.06% in the diet) consisting of cycles of 3 wk on the carcinogen followed by 1 wk on a normal diet, with four cycles representing a full carcinogenic exposure. At weekly intervals, postmitochondrial (S9) and postmicrosomal liver fractions were isolated from the rats and tested for their ability to activate FAA and N-hydroxy-FAA to metabolites mutagenic for *Salmonella typhimurium* TA1538. FAA exposure resulted in an almost immediate enhancement of S9 (mutation-producing) activity, which reached a max of 300% by the end of Cycle 1. Although still elevated through Cycle 2, S9 activity declined rapidly and was severely depressed during the remainder of the feeding regimen. The diminished ability of the microsomal system to activate the parent compound was striking when hepatic nodules were tested separately and compared with surrounding parenchyma or control liver. Throughout the same exposure period, the activity of the postmicrosomal fraction was relatively unaltered. The decrease of S9 activity was accompanied by a decline in microsomal protein levels. The reduced mutagenizing activity of the liver microsomes is in accord with recent results indicating a decline in drug-metabolizing activity during chemical hepatocarcinogenesis. (22 refs)

78-2653 **Gangliosides of Liver Tumors Induced by N-2-Fluorenylacetamide. I. Ganglioside Altera-**

tions in Liver Tumorigenesis and Normal Development. (Eng) Merritt, W. D. (Section Cytology, Yale Univ. Sch. Medicine, New Haven, CT, 06510); Richardson, C. L.; Keenan, T. W.; Morre, D. J. *J Natl Cancer Inst* 60(6): 1313-1327; 1978.

Ganglioside patterns were studied in hyperplastic liver nodules and hepatomas induced in Wistar rats by a low-protein diet containing 0.05% of the carcinogen N-2-fluorenylacetamide (2-AAF). The patterns were compared with those in the livers of fetal, newborn, and normal adult rats. Ganglioside sialic acid levels were elevated in the nodules and hepatomas, and the levels were higher in fetal than in adult liver. Monosialogangliosides and disialogangliosides were evenly distributed in normal adult liver, but the monosialogangliosides predominated in 2-AAF-treated livers. Superficially at least, the ganglioside changes during tumorigenesis mimicked the reversal of liver differentiation. The enzyme that converts lactosylceramide to G-M3 was one of the earliest to show increased activity in hyperplastic tissues and the tissues surrounding nodules; a transient rise in G-M2 in newborn rat liver was duplicated by the high G-M2 levels in well-circumscribed, poorly differentiated hepatomas; and G-M3 levels were highest in fetal liver and in well-differentiated hepatomas. G-D1a levels were also elevated in fetal tissues and hepatomas, compared with normal adult liver. It is concluded that the ratio of higher monosialogangliosides to higher disialogangliosides is highest in fetal tissue, lowest in the adult, and correlated with increasing tumorigenicity. (61 refs)

78-2663 **Carcinogenic and Antitumor Effects of Aminotriazole on Acatalasemic and Normal Catalase Mice.** (Eng) Feinstein, R. N. (Div. Biological and Medical Res., Argonne Natl. Lab., Argonne, IL, 60439); Fry, R. J.; Staffeldt, E. F. *J Natl Cancer Inst* 60(5): 1113-1116; 1978.

The carcinogenic and antitumor effects of 3-amino-1H-1,2,4-triazole (AT) were evaluated in two inbred mouse strains, C3H and C57BL/6, and their corresponding acatalasemic (a-cat) substrains in order to determine the effect of catalase on tumor susceptibility. Natural tumor incidences, susceptibility to γ-radiation induction (4 weekly doses of 175 rads, 45 rads/

min, from a ^{60}Co source) of thymic lymphomas, and the effect of neutron radiation (1 dose of 80 rads, 15 rads/min) on thyroid tumors were compared in relation to the presence or absence of the mutation at the gene locus for catalase and the effect of AT (1% in the diet ad libitum). Prolonged consumption of an AT diet shortened the lives of all mice, although significant differences existed between strains and substrains. The a-cat mice of both strains survived longer (mean, 35 wk) than their normal catalase (n-cat) counterparts (mean, 25 wk). A larger proportion of the former (21/87), especially those of strain C3H, developed liver tumors that were detected earlier (35 wk) than the n-cat mice (6/85, 50 wk). Thyroid tumors were less common because they required a longer period of development. The antitumor effects of AT included a delay in the appearance of mammary tumors, a striking reduction in γ-radiation induced lymphomas, and a sharp reduction in neutron radiation-induced harderian gland and ovarian tumors. The fact that on the AT diet, C3H a-cat mice developed more liver tumors, starting earlier, than the n-cat substrain indicates a possible relevance of catalase and H_2O_2 in carcinogenesis. The increased incidence of liver tumors in AT-treated a-cat mice was probably due to the diminished rate of degradation of endogenous H_2O_2. (30 refs)

The effect of the purine bases adenine and guanine on malformations produced in the hamster embryo by ribavirin (RV), an antineoplastic agent, was investigated. On day 8 of gestation, golden hamsters were given ip injections of RV (2.5 or 5.0 mg/kg) alone, either of the purine bases (100 mg/kg) alone, or combinations of RV + adenine and/or guanine. RV produced a broad spectrum of anomalies in the developing hamster, but adenine or guanine produced no gross external developmental malformations. RV + guanine + adenine increased the percentage of resorbed implantation sites and the percentage of malformed hamster fetuses significantly compared with RV alone. The simultaneous injection of 2.5 mg/kg RV + adenine increased only slightly the number of embryonic deaths, but 5.0 mg/kg RV + adenine significantly increased both the number of embryonic deaths and the number of malformed fetuses. A similar experimental protocol with RV + guanine did not result in a highly significant increase in the number of resorptions or the number of malformed hamsters. However, the total number of malformations of the eyes, limbs, and ribs in offspring of hamsters treated with 5.0 mg/kg RV + guanine was greater than the number in fetuses recovered from dams treated with RV alone. The fetal anomalies produced by the RV-purine combinations were generally more severe than those produced by an equivalent amount of RV alone. (10 refs)

78-2668 **The Effect of Bran on Dimethylhydrazine-induced Colon Carcinogenesis in the Rat.** (Eng) Barbolt, T. A. (Center Experimental Pathology and Toxicology, Albany Medical Coll., Albany, NY, 12208); Abraham, R. *Proc Soc Exp Biol Med* 157(4): 656-659; 1978.

The role of dietary fiber in dimethylhydrazine (DMH)-induced colon carcinogenesis was investigated in rats. Four groups of 10 male Sprague-Dawley rats each were used: Group I - control; Group II - 30 mg/kg DMH po weekly for 10 doses; Group III - 20% wheat bran in the standard diet; and Group IV - bran and DMH. Intestinal transit times and fecal output were estimated during the 16th, 17th, and 20th weeks. The rats were killed at 21 wk, and the intestinal tract was examined grossly and microscopically for tumors. Intestinal transit times were decreased and fecal outputs increased in rats given the 20% bran diet. In Group II, all 10 rats had tumors, with a mean of 6.4 tumors/rat. In Group IV, 6/9 rats had tumors, with a mean of 1.8 tumors/rat/group and 2.7 tumors/rat that had tumors. The size and distribution of these tumors were similar in both groups. Bran in the diet had little effect on the incidence, number, or distribution of duodenal tumors. The close proximity of the duodenal tumors to the opening of the common bile duct suggests that an active metabolite of DMH was being excreted directly into the bile or that the local high bile salt concentration was acting to promote tumorigenesis in this area. 78-2672 **Histogenesis of Symmetrical 1,2-Dimethylhydrazine-induced Neoplasms of the Colon in the Mouse.** (Eng) Chang, W. W. (Dept. Anatomy, Mount Sinai Sch. Medicine, City Univ. New York, One Gustave L. Levy Place, New York, NY, 10029). *J Natl Cancer Inst* 60(6): 1405-1418; 1978.

CF-1 female adult mice were given weekly sc injections of 20 mg/kg symmetrical 1,2-dimethylhydrazine (DMH)·2HCl and killed at intervals of 9-36 wk after the initial injection. ^{3}H-thymidine (TdR) was given before sacrifice. The histogenesis of colon neoplasms was investigated by means of autoradiographs prepared from sections of Epon-embedded descending colon, which were stained with the PAS reaction and iron hematoxylin. By 9 wk after initiation of DMH treatment, the distal 5 cm of the colon was enlarged, the mucosa thickened, and the crypts were elongated and hyperplastic. Although the number of proliferating cells increased in the hyperplastic crypts, the distribution of ^{3}H-TdR-labeled cells in these crypts was similar to that in the normal crypts. Differentiation and transformation of epithelial cells occurred, but somewhat aberrantly. The cryptal hyperplasia was diffuse, but the neoplasms that began to appear by 9 wk after the initial treatment were localized lesions. An isolated crypt from which a neoplasm developed was first repopulated by what appeared to be altered, undifferentiated 'stem' cells. These cells did not differentiate,they continued to divide, and eventually they accumulated in the upper part of the crypts, where the earliest identifiable neoplastic lesion was observed. The early lesions expanded in various directions, depending on the local environments, and formed polypoid or discoid lesions. The biologic behavior of a neoplasm seemed to be determined by the downward progression of its leading edge. When it penetrated the muscularis mucosae, the neoplasm became highly invasive. In the murine model, invasive adenocarcinomas were observed 26 wk after the start of DMH treatment. (43 refs)

78-2674 **Alkyl Methane Sulfonate Mutation of Diploid Human Lymphoblasts and *Salmonella typhimurium*.** (Eng) Hoppe, H. (Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA, 02139); Skopek, T. R.; Liber, H. L.; Thilly, W. G. *Cancer Res* 38(6): 1595-1600; 1978.

The concentration dependence of mutation in equigenerational exposures to methyl, ethyl, propyl, and butyl methanesulfonate (M-, E-, P-, and BMS) was determined in MIT-2 diploid human fibroblasts and *Salmonella typhimurium*. Forward mutations were measured at the hypoxanthine-guanine phosphoribosyltransferase locus in human lymphoblasts and at the putative guanine phosphoribosyltransferase locus in *S. typhimurium*. Reverse mutations at the *his* G46 locus were also measured in *S. typhimurium*. Studies with the human cells indicated that there was decreasing toxicity with increasing chain length. The concentration required to reduce the surviving fraction to 0.10 was 0.05 mM for MMS, 0.44 mM for EMS, 1.2 mM for PMS, and 1.4 mM for BMS. A similar relationship between mutagenic potential and chain length was observed for EMS, PMS, and BMS; the MMS mutant fraction increased with concentration initially, but the extreme toxicity prevented accurate determination of the mutant fraction. With *S. typhimurium*, the concentration necessary to reduce the surviving fraction to 0.10 was 10 mM for MMS and >20 mM for BMS, PMS, and EMS. For both MMS and EMS, concentration dependence differed significantly from that expected from single-hit kinetics on a target of fixed size. In the reverse mutation studies, the concentration required to induce a mutant fraction approx tenfold over controls was 5 mM for MMS, 10 mM for EMS, 30 mM for PMS, and 10 mM for BMS. This study and previous reports support the conclusion that *S. typhimurium* and mammalian cells are essentially equisensitive to the mutagenic effects of EMS when concentration and exposure time are taken into account. The forward and reverse mutation assays in *S. typhimurium* revealed no important differences in sensitivity among the four compounds. (39 refs)

78-2676 **Inhibiting Effect of Caffeine on Spontaneous and Urethan-induced Lung Tumors in Strain A**

Mice. (Eng) Theiss, J. C. (Dept. Community Medicine, Sch. Medicine, Univ. California at San Diego, La Jolla, CA, 92093); Shimkin, M. B. *Cancer Res* 38(6): 1757-1761; 1978.

The anticarcinogenic effect of caffeine on the development of spontaneous and urethan-induced lung tumors in strain A mice was investigated. Ip injections of 8, 20, or 40 mg/kg caffeine thrice weekly for 8 wk suppressed spontaneous pulmonary adenoma development. They also suppressed urethan-induced (0.25 and 1.0 mg/g sc) lung tumor development when they were begun 1 wk before urethan administration, but this suppression was not significant when caffeine treatment was initiated 1 wk after urethan injection. The most pronounced suppression of lung tumor formation occurred when caffeine was given as only two injections 3 hr before and 3 hr after urethan administration. The incorporation of ^{3}H-thymidine into lung tissue DNA of caffeine-treated mice was impaired at the time of urethan administration. Caffeine also partially antagonized the effects of urethan on lung tissue. It is suggested that caffeine-induced suppression of DNA synthesis interferes with pulmonary adenoma induction by decreasing the affinity of lung tissue DNA for urethan. The finding that chronic caffeine treatment produced continued suppression of thymidine incorporation into lung tissue DNA suggests that caffeine-induced inhibition of spontaneous pulmonary adenoma formation is due to a general suppression of lung DNA synthesis. 78-2681 **Histological Examination of Perinatal Eye Development in the Rat after Ingestion of Sodium Cyclamate and Sodium Saccharin During Pregnancy.** (Eng) Luckhaus, G. (Institut fur Toxikologie der Bayer AG, Postfach 101709, D5600 Wuppertal 1, W. Germany); Machemer, L. *Food Cosmet Toxicol* 16(1): 7-11; 1978.

Pregnant female Wistar rats were fed a diet containing 5% sodium cyclamate or 0.4% sodium saccharin for 20 days after mating. The daily ingested dose was 1,495 mg for the cyclamate animals, 98.8 mg for the saccharin group. Examination of the fetuses on day 20 of pregnancy or the young at 3 wk of age revealed no histological changes in the lens, vitreous body, insertion of the optic nerve, or other parts of the eye. (11 refs)

78-2682 **The Fate of Saccharin Impurities. The Excretion and Metabolism of [^{14}C]Toluene-4-sulphonamide and 4-Sulphamoyl[^{14}C]benzoic Acid in the Rat.** (Eng) Ball, L. M. (Pharmacology Branch, NIEHS, Research Triangle Park, NC, 27709); Williams, R. T.; Renwick, A. G. *Xenobiotica* 8(3): 183-190; 1978.

The fate of ^{14}C-labeled toluene-4-sulfonamide (TS) and 4-sulfamoylbenzoic acid (SBA), byproducts of saccharin synthesis by the Remsen-Fahlberg process, was determined in female albino Wistar rats. The rats were given 29 or 200 mg/kg TS or 22 mg/kg SBA by intragastric intubation. Approx 94% of the SBA dose was eliminated within 24 hr. By 6 days, 73%-83% of the dose was recovered in the urine, but significant amounts (18%-32%) were eliminated in the feces because of incomplete absorption. The ^{14}C in the urine and feces was unchanged SBA. No labeled CO_2 was detected in the expired air. Following TS administration, 66%-89% of the dose was rapidly eliminated in the urine, with only 2%-8% being eliminated in the feces. The label in the feces was SBA; it probably originated in the tissues, since the gut flora could not effect this biotransformation. The urine of rats given TS contained SBA as the major metabolite (93% of the urinary label), together with small amounts of unchanged TS (1.5%-2.3% of the label), 4-sulfamoylbenzyl alcohol (2.0%-3.9%), 4-sulfamoylbenzaldehyde (0%-1.5%: at the lower dose only), and N-acetyltoluene-4-sulfonamide (2.1%-2.3%: at the higher dose only). Thus, prolonged intake of saccharin containing traces of TS and SBA should not lead to their accumulation in the body, providing that the larger amounts of saccharin do not interfere with the oxidation of TS to SBA or the renal elimination of the latter. (14 refs)

78-2683 **Methyl Methanesulphonate Mutagenesis in L5178Y Mouse Lymphoma Cells.** (Eng) Cole, J. (M.R.C. Cell Mutation Unit, Univ. Sussex, Falmer, Brighton BN1 9QG, England); Arlett, C. F. *Mutat Res* 50(1): 111-120; 1978.

The effect of short (2 hr) and long (20 hr) treatment times on methyl methanesulfonate (NMS) mutagenesis was determined in murine lymphoma L5178 cells. At time 0 posttreatment, treatment of the cells for 20 hr with 0.048 mM MMS reduced cloning efficiency to 74.0%; treatment for 2 hr with 0.12, 0.24, 0.48, and 0.96 mM MMS reduced cloning efficiency to 99.6%, 90.2%, 47.5%, and 1.5%, respectively. Recovery, measured by cloning efficiency at 24-hr intervals after treatments that inflicted >25% lethality, was delayed for 72-96 hr. There was no detectable cell multiplication for 72 hr in the population with a 98.5% level of kill. There was a dose-dependent induction of thioguanine-resistant (TG-r) and thymidine-resistant (TdR-r) variants, but not ouabain-resistant (Oua-r) variants. TdR-r variants were expressed much earlier (48-96 hr) than TG-r variants (144 hr). (24 refs)

78-2686 **Post-Treatment with Caffeine and the Induction of Gene Mutations by Ultraviolet Irradiation and Ethyl Methanesulphonate in V-79 Chinese Hamster Cells in Culture.** (Eng) van Zeeland, A. A. (Dept. Radiation Genetics and Chemical Mutagenesis, State Univ. Leiden, Wassenaarseweg 72, Leiden, Netherlands). *Mutat Res* 50(1): 145-151; 1978.

A determination was made of the effect of caffeine posttreatment on the induction of 6-thioguanine-resistant mutants in V-79 Chinese hamster cells by UV radiation and ethyl methanesulfonate (EMS). Caffeine (1 mM) potentiated the killing effect of UV radiation and EMS. However, it did not alter the induction of mutations at the hypoxanthine-guanine phosphoribosyltransferase locus by UV radiation (up to a fluence of 4 joules/m^2) or by EMS (up to a concentration of 50 mM). The results are consistent with the theory that caffeine partially inhibits an error-prone postreplication repair mechanism without changing the mutation frequency. (26 refs)

78-2687 **The Association Between Mutagenicity and Adduct Formation of 1,2,7,8-Diepoxyoctane and 1,2,5,6-Diepoxycyclooctane.** (Eng) Huang, S. L. (Lab. Envi
ronmental Mutagenesis, Natl. Inst. Environmental Healt
Sciences, NIH, Research Triangle Park, NC, 27709); Rader
D. N.; Lee, C. Y. *Chem Biol Interact* 20(3): 333-340; 1978

The mutagenicity of 1,2,5,6-diepoxycyclooctane (DECO
and 1,2,7,8-diepoxyoctane (DEO) was investigated in diploi
Chinese hamster lung cells. 6-Thioguanine (6-TG) resistanc
was the marker for mutagenicity testing: DEO was genetica
ly active, but DECO was totally inactive. The frequencies c
DEO-induced mutations to 6-TG resistance were dose-de
pendent. DEO readily formed adducts with radiolabeled nu
cleotides, as demonstrated by thin-layer chromatography an
the shift of the UV absorption max in DEO/nucleotide mix
tures. There was no formation of adducts between radionu
cleotides and DECO. The difference between the chemica
and genetic activities of the two compounds was attribute
to their molecular conformations and the resulting differen
tial flexibilities and adduct-forming abilities. The associatio
between mutagenicity and adduct formation was conclusive
(25 refs)

78-2688 **Squamous Lesions in Lungs of Rats Exposed t
Tobacco-Smoke-Condensate Fractions by Re
peated Intratracheal Instillation.** (Eng) Simons, P. J. (Hazle
ton Labs. Europe Ltd., Otley Road, Harrogate HG3 1PY
England); Lee, P. N.; Roe, F. J. *Br J Cancer* 37(6): 965-97
1978.

Twice-weekly intratracheal instillations in specific-path
gen-free Wistar rats of up to 24 mg of the tobacco smok
condensate caffeine-complexing fraction [Fraction (R
P)G] suspended in either infusine (I) or buffered saline/gel
tin (BS/G) gave rise to foci of squamous metaplasia of alve
lar epithelium (SqM) and squamous neoplasms (SqN). Fra
tion (R + P) G, which is almost as tumorigenic for mous
skin as the nearly 30 times larger mass of condensate fro
which it is derived, could be given in this way for up to
wk without excessive mortality or any marked effect on th
rate of body-wt gain. By contrast, similar treatment wit
Fraction N(QG), a fraction having very low tumorigenic a
tivity for mouse skin, induced no SqN and barely an exce
of SqM over that induced by either vehicle alone. The effec
of Fraction (R + P)G on the incidence of SqM and SqN we
both time- and dose-related, the effect on SqM incidence b
ing evident after 10 wk of treatment. No SqN seen we
unequivocally malignant; however, because of the design
the experiment, only 5 rats exposed to Fraction (R + P)
were observed >60 wk after the start of the experiment. Ot
er changes in the lung, including aggregates of alveolar ma
rophages laden with golden-brown pigment and foci of cubo
dal/columnar metaplasia of alveolar epithelium, we
frequently seen in response to both fractions. Fraction (R
P)G administered in I was more effective in causing SqM an
SqN than the same fraction administered in BS/G. The in
plications of the findings are discussed, particularly the pos
bility that the intratracheal instillation technique might

seful as a rapid bioassay for comparing the tumorigenicity f different cigarette smoke condensates. (13 refs)

8-2689 **The Mutagenicity of Cigarette Smoke Condensate in *Saccharomyces cerevisiae* (Meeting bstract).** (Eng) DeMarini, D. M. (Illinois State Univ., ormal, IL, 61561). *Mutat Res* 53(1): 84; 1978. (no efs)

8-2690 **Chemical Studies on Tobacco Smoke-LIV Determination of Hydroxybenzyl Alcohols and Hydroxyphenyl Ethanols in Tobacco and Tobacco Smoke.** Eng) Hecht, S. S. (Naylor Dana Inst. Disease Prevention, merican Health Foundation, Valhalla, NY, 10595); Carmella, S.; Hoffmann, D. *J Anal Toxicol* 2(2): 56-59; 1978.

ince 2-(p-hydroxyphenyl)-ethanol (PHPE) and m-hydroxybenzyl alcohol (MHBA) produced hyperplasia in mouse skin nd thus could contribute to the tumor-promoting and cocarcinogenic activity of cigarette smoke condensate, a method was developed for their quantitation in tobacco and tobacco moke. The method consists of solvent partitions followed by preparative thin-layer chromatography and gas-liquid hromatography of the silylated hydroxyphenyl alcohol fraction. The major source of PHPE in mainstream smoke was ransferred from tobacco, but MHBA was formed, at least partially, from cellulose. (14 refs)

78-2691 **Fractionation of Cigarette Smoke Condensate for Chemical and Biological Testing.** (Eng) Walters, D. B. (Natl. Inst. Environmental Health Services, Environmental Biology and Chemistry Branch, P.O. Box 12233, Research Triangle Park, NC, 27709); Chamberlain, W. J.; Akin, F. J.; Snook, M. E.; Chortyk, O. T. *Anal Chim Acta* 99(1): 143-150; 1978.

Gel filtration and silicic acid column chromatography were used to separate the three fractions that account for most of the tumorigenicity of cigarette smoke condensate (CSC): the ether-soluble weak-acid fraction (F-8); the polycyclic aromatic hydrocarbon (PAH) fraction (F-55); and a polar, neutral lipid fraction (F25 + 26). Biological activity was concentrated in subfractions containing significantly smaller percentages of initial CSC wt, and various groups of compounds were concentrated into individual subfractions, facilitating chemical and biological analyses. F-8 was separated into four subfractions containing fatty acids, phenols, polyphenols, phenolic acids, and other high-mol-wt materials. F-55 was separated into two subfractions, one of which contained essentially pure PAH's (0.01% by wt of CSC). F-25 + 26 was separated into three subfractions containing glycolipids, sterol glucosides, and other high-mol-wt materials. Mouse-skin-painting experiments showed that F-8 had significant tumorigenic activity (48.5% tumor bearers). A subfraction of F-8, in which catechol was concentrated and which comprised 3.27% CSC, was also tumorigenic (30.7% tumor bearers), as was a combination of this subfraction, the active PAH subfraction, and a neutral lipid subfraction. The results indicate that catechol may be a potent cocarcinogen and that the PAH's in CSC interact with other components to exert a tumorigenic effect. (12 refs)

78-2692 **In Vitro Morphological Transformation of Cryopreserved Hamster Embryo Cells with Tobacco Tar.** (Eng) Takayama, S. (Dept. Experimental Pathology, Cancer Inst., Kami-Ikebukuro 1-327-1, Toshima-ku, Tokyo 170, Japan); Katoh, Y.; Hirakawa, T.; Tanaka, M. *Gann* 69(1): 85-90; 1978.

The in vitro transformation of cryopreserved line 7602 hamster embryo cells by tobacco tar and its hexane (NA-1), benzene (NA-2), ethyl acetate (NA-3), and methanol (NA-4) acidic or neutral fractions and its ether (B-1) and methanol (B-2) basic fractions was investigated. Line 7602 was chosen over six other hamster embryo cell lines, as it had the best response to transformation by 3-methylcholanthrene. Neither the tobacco tar nor any of its fractions were cytotoxic at doses of 0.5 to 5.0 μg/ml. A significant number of transformed colonies were induced by NA-4 at levels of 1 and 5 μg/ml. The tobacco tar and fractions NA-2, NA-3, and B-2 also induced a significant number of transformed colonies. The tar and all four fractions have been reported to be potent mutagens in bacterial systems. Fractions NA-1 and B-1 did not show any transforming or mutagenic activity. These findings indicate that a close correlation exists between in vitro morphological transformation and bacterial mutagenicity. (16 refs)

78-2693 **Protection of Hamster Lung Cultures by L-Cysteine or Vitamin C Against Carcinogenic Effects of Fresh Smoke from Tobacco or Marihuana Cigarettes.** (Eng) Leuchtenberger, C. (Dept. Cytochemistry, Swiss Inst. Experimental Cancer Res., Rue du Bugnon 21, 1011 Lausanne, Switzerland); Leuchtenberger, R. *Br J Exp Pathol* 58(6): 625-634; 1977.

Hamster lung cultures, when grown in normal medium (NM) and exposed to fresh smoke from tobacco or marihuana cigarettes for 1-8 wk, displayed cytotoxic alterations, loss of lysosomes, and abnormalities of cell division and chromosome DNA content. Cultures grown in NM in the presence of L-cysteine showed an increase of lysosomes and significantly less abnormalities in cell division and DNA content of chromosomes. Cultures grown in NM and exposed to smoke for 9-24 wk showed rapid irregular growth of fibroblasts and/or malignant transformation, but cultures grown in L-cysteine-containing NM and exposed to smoke closely resembled nonexposed controls. Addition of vitamin C to NM had an effect similar to that of L-cysteine. Cultures grown in NM that had undergone malignant transformation continued their abnormal growth during the 2-yr test period. When these transformed cultures were grown for 3 mo or longer in the presence of L-cysteine or vitamin C, growth became more normal, and the cultures closely resembled those of nonexposed controls. These results suggest that, in hamster lung cultures, addition of L-cysteine or vitamin C protects against or reverses abnormal growth and malignant transformation occurring after repeated exposure to smoke. The increase of lysosomes after L-cysteine or vitamin C was added to the media suggests the possible importance of lysosomes in protecting the cultures against the enhancement of carcinogenesis by smoke. (25 refs)

78-2694 **Tobacco-specific Nitrosamines: Formation from Nicotine In Vitro and During Tobacco Curing and Carcinogenicity in Strain A Mice.** (Eng) Hecht, S. S. (Div. Environmental Carcinogenesis, Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Chen, C. B.; Hirota, N.; Ornaf, R. M.; Tso, T. C.; Hoffmann, D. *J Natl Cancer Inst* 60(4): 819-824; 1978.

The formation of tobacco-specific nitrosamines from nicotine, the major tobacco alkaloid, was examined. Detached leaf tobacco was fed either labeled nicotine or nornicotine and air-cured. The cured leaf was then examined for labeled N′-nitrosonornicotine (NNN). The yield of NNN was 0.007% from nornicotine and 0.009% from nicotine. Because the ratio of nicotine to nornicotine in conventional nicotine-type tobacco is 20-100:1, nicotine is considered to be the major precursor of NNN in tobacco. The formation of other nitrosamines from nicotine in vitro was then investigated. Reaction of nicotine with $NaNO_2$ gave rise to NNN, 4-(N-methyl-N-nitrosamino)-1-(3-pyridyl)-1-butanone (NNK) and 4-(N-methyl-N-nitrosamino)-4-(3-pyridyl)butanal (NNA). An analysis of market products revealed 0.6-2.4 μg NNK/g chewing tobacco and snuff. The three compounds were then tested for carcinogenicity in female A/J mice. The animals were given ip injections of 22 mg of the compounds three times weekly for 22 injections. NNK in trioctanoin induced lung adenomas in 20/23 animals, compared with 16/21 for NNN in saline, 12/23 for NNN in trioctanoin, and 9/25 for NNA in saline. Furthermore, two cases of undifferentiated carcinoma of the salivary glands occurred in the NNN group. Since the hazardous compounds were formed during curing, methods should be developed to reduce their concentrations in both tobacco and smoke. (32 refs)

78-2695 **Nitrate and Gastric Cancer (Meeting Abstract).** (Eng) Tannenbaum, S. R. (Massachusetts Inst. Technology, Cambridge, MA). *Digestion* 16(3): 279; 1977. (no refs)

78-2696 **Hypothesis for the Aetiology of Gastric Cancer (Meeting Abstract).** (Eng) Ruddell, W. S. (Dept. Gastroenterology, Central Middlesex Hosp., London, England); Hill, M. J.; Walters, C. L. *Digestion* 16(3): 272; 1977. (no refs)

78-2697 **Nitrite Studies in Oesophageal Cancer.** (Eng) Lowenfels, A. B. (Westchester County Medical Center, Valhalla, NY); Tuyns, A. J.; Walker, E. A.; Roussel, A. *Gut* 19(3): 199-201; 1978.

Salivary and gastric nitrite levels were studied in 20 patients with esophageal cancer and 15 healthy controls. A basal saliva sample was obtained prior to the ingestion of 100 ml of beet juice containing 160 mg nitrate; a second saliva sample were obtained 90 min later. Basal nitrite levels were significantly higher in controls (115 μM) than in cancer patients (48 μM). Following administration of the beet juice, the levels increased significantly in both groups (913 and 674 μM, respectively), and the difference between the groups lost its significance. The mean pH of the gastric juice of seven patients with a gastronomy was 3.5, and the mean gastric juice nitrite concentration was 1.3 μM. Since both groups had similar ability to convert nitrate to nitrite in the saliva, it is suggested that this factor is less important for the in vivo formation of nitrite than the amount of nitrate in the diet. (14 refs)

78-2698 **Organotropic Effect of N-Bis(2-hydroxypropyl)nitrosamine: Production of Lung and Liver Tumors by Its Oral Administration in Mice.** (Eng) Konishi, Y. (Dept. Oncological Pathology, Cancer Center, Nara Medical Univ., 840 Shijo-cho, Kashihara, Nara-ken 634, Japan); Kondo, H.; Inui, S.; Denda, A.; Ikeda, T.; Kojima, K. *Gann* 69(1): 77-84; 1978.

The organotropic effect of N-bis(2-hydroxypropyl)nitrosamine (DHPN), a postulated metabolite of dipropylnitrosamine, was studied in male dd mice. The mice were divided into five groups: Group 1 served as controls, and Groups 2-5 received 100, 250, 500, or 1,000 ppm DHPN, respectively, in the drinking water. The animals were sacrificed 16 wk after the beginning of the experiment. Each mouse in Groups 2-5 ingested 6.3, 13.9, 22.4, and 34.2 mg DHPN/day, respectively. Lung tumors were noted in 10/11 Group 2 animals (10 adenomas, 1 adenocarcinoma), 9/11 Group 3 animals (adenomas), 8/11 Group 4 animals (8 adenomas, 2 adenocarcinomas), and 8/14 Group 5 animals (8 adenomas, 1 adenocarcinoma). Liver tumors were noted in 8 Group 2 animals (hemangiomas), 8 Group 3 animals (hemangiomas), 8 Group 4 animals (8 hemangiomas and 8 hemangioendotheliomas), and 14 Group 5 animals (3 hemangiomas, 3 hemangioendotheliomas, 8 hemangioendothelial sarcomas). No lung or liver tumors were found in Group 1 animals. Furthermore, no pancreatic tumors, which have been found in hamsters, were found. These results are similar to those previously reported for rats and guinea pigs. (27 refs)

78-2699 **Bladder Tumors Induced in Dogs by N-butyl -N- (4-hydroxybutyl)-nitrosamine — Scanning Electron Microscopic Observation (Meeting Abstract).** (Jpn) Hirao, Y. (Nara Medical Univ., Kashihara, Nara pref., 634, Japan); Kondoh, T.; Yamada, K.; Babatani, K.; Ohara, S.; Aoyama, H.; Watanabe, H.; Hashimoto, M.; Okajima, E. *Jpn J Urol* 68(9): 864-865; 1977. (no refs)

78-2700 **Effects of Sex Hormones on Oncogenesis in Rat Urinary Bladder by N-Butyl-N-(4-hydroxybutyl)-nitrosamine.** (Eng) Kono, N. (Dept. Urology, Tokyo Electric Power Hosp., 9-2, Shinanomachi, Shinjuku-ku, Tokyo, Japan); Tanahashi, T.; Suzawa, N.; Azuma, C. *Int J Clin Pharmacol Biopharm* 15(3): 101-105; 1977.

The effects of sex hormones on N-butyl-N-(4-hydroxybutyl)-nitrosamine (BBN)-induced carcinogenesis in the bladders of male Wistar-Imamichi rats were evaluated. Eight-week-old rats were divided into five treatment groups: (1) 30 ml drinking water supplemented with 0.02 mg/head/day of BBN for 8 wk; (2-4) BBN + testosterone propionate, estradiol benzoate, or estriol tripropionate, the hormones given in a dose of 3 mg/kg/wk im for 20 wk; (5) untreated. The incidence of hyperplasia in the respective groups was 2/25, 2/23, 5/23, 3/24, and 0/25. The corresponding incidence of bladder tumors was 6/25, 9/23, 2/23, 2/24, and 0/25. There were statistically significant differences in bladder tumor incidence between Groups 2 and 3 and between Groups 2 and 4. It is concluded that external sex hormones can influence experimental oncogenesis in the male rat bladder. (11 refs)

78-2701 **Promoting Effect of DL-Tryptophan and Saccharin in Urinary Bladder Carcinogenesis in the Rat (Meeting Abstract).** (Eng) Cohen, S. M. (Dept. Pathology, St. Vincent Hosp., Worcester, MA, 01504); Arai, M.; Friedell, G. H. *Proc Am Assoc Cancer Res* 19: 4; 1978. (no refs)

78-2702 **Induction of Transitional Cell Carcinoma of the Urinary Bladder in Rats by Feeding N-[4-(5-Nitro-2-furyl)-2-thiazolyl]formamide. Histological and Ultrastructural Findings.** (Eng) Adolphs, H. D. (Dept. Urology, Univ. Bonn, D-5300 Bonn-Venusberg, W. Germany); Thiele, J.; Kiel, H.; Steffens, L. *Urol Res* 6(1): 19-27; 1978.

Female Wistar rats were fed a diet containing 0.188% N-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide (FANFT) for 8 mo, at an average FANFT consumption of 0.195 g/wk. One animal was sacrificed each month for investigation by light and electron microscopy, and the remaining animals were killed after 12 mo. There was a 100% incidence of bladder tumors in the rats after 8 mo on the FANFT-containing diet. The first definite alterations of the mucosa were apparent after 5-6 mo of FANFT feeding. Histological changes of the urothelium consisted of various degrees of hyperplasia and dysplasia. An infiltrating transitional cell carcinoma first appeared after 8 mo. Electron microscopy showed microvillous transformation of the luminal plasma membrane and the appearance of a thick fluffy cell coat (glycocalyx). These changes are explained by an altered function of the Golgi complex that occurs during malignancy and leads to a loss of the specific discoid vesicles of the urothelial cell. The electron microscopic findings showed that the transitional cell carcinoma induced by FANFT is identical to the papillary carcinoma of man, indicating the usefulness of this model for studying new methods of therapy in papillary carcinoma of the urinary bladder. 78-2703 **Differences in Binding of Nitrosamines to Cytochrome P 450. Possible Relevance for Their Activation and Inactivation (Meeting Abstract).** (Eng) Appel, K. E. (Dept. Molecular Toxicology, German Cancer Res. Center, D-6900 Heidelberg, W. Germany); Kunz, H. W. *Naunyn Schmiedebergs Arch Pharmacol* 302(Suppl): R20; 1978. (no refs)

78-2704 **Cytochrome P-450 and the Activation of Aflatoxin B$_1$ in *Saccharomyces cerevisiae* (Meeting Abstract).** (Eng) Callen, D. F. (Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC, 27709); Philpot, R. M.; Ong, T. M. *Mutat Res* 53(1): 85; 1978. (no refs)

78-2705 **Aryl Hydrocarbon Hydroxylase Activity and Microsomal Cytochrome Content of Human Fetal Tissues.** (Eng) Rifkind, A. B. (Dept. Pharmacology, Cornell Univ. Medical Coll., New York, NY, 10021); Tseng, L.; Hirsch, M. B.; Lauersen, N. H. *Cancer Res* 38(6): 1572-1577; 1978.

The suitability of prostaglandin (PG) abortuses for the study of mixed function oxidase activity was examined. Aryl hydrocarbon hydroxylase (AHH) was used as an index of mixed-function oxidation and as an indirect indicator of tissue capacity to activate polycyclic hydrocarbons and microsomal cytochrome content. Tissues were obtained from human fetuses aborted by (a) ia PG F$_2\alpha$, (b) im PG 15-methyl-F$_2\alpha$, (c) vaginal suppositories containing PG E$_2$ (20 mg every 2 hr until abortion), (d) intravaginal Silastic devices containing PG 15 (S)-15-methyl-$F_2\alpha$ (11 mg), and (e) hysterotomy performed for medical reasons. Cytochrome P-450 concentrations and AHH activity were approx 4 times higher in adrenal glands than in liver. AHH levels in testes, ovaries, vagina, and uterus were greater than or equal to those in the liver, but levels in lung, kidney, and intestines were lower than those in the liver. Mean hepatic AHH and hepatic and adrenal cytochromes P-450 and b_5 were not significantly different in PG and hysterotomy abortuses. Mean adrenal AHH was significantly lower in PG abortuses (95.1 vs 228.4 picomoles phenol/mg protein/hr for hysterotomy), but the ranges in both groups were overlapping. Neither maternal cigarette smoking habit nor fetal sex affected hepatic or adrenal AHH activity or microsomal cytochrome concentrations or difference spectra. Hepatic and adrenal AHH activities were concentrated in microsomes and were correlated with microsomal P-450 content. These findings are consistent with P-450 mediation of AHH in human fetal tissues. The data demonstrate the utility of PG abortuses for studies of fetal tissue mixed-function oxidase activity and point to the endocrine glands and target tissues in addition to the liver as potential sites for activating chemical carcinogens and cytotoxins in the human fetus. (35 refs)

78-2706 High Mutagenicity of N-(α-Acyloxy)alkyl-N-alkylnitrosamines in *S. typhimurium*: Model Compounds for Metabolically Activated N,N-Dialkylnitrosamines. (Eng) Camus, A. M. (Unit Chemical Carcinogenesis, International Agency Res. Cancer, 69008 Lyon, France); Wiessler, M.; Malaveille, C.; Bartsch, H. *Mutat Res* 49(2): 187-194; 1978.

Several N,N-dialkylnitrosamines monosubstituted at the α-carbon with an acetoxy group were tested for their mutagenic activity in *Salmonella typhimurium* TA1530 in the presence or absence of an S-9 rat liver mix. In the absence of S-9 enzymes, the mono-α-acetoxy derivatives of N-ethyl-N-methylnitrosamine and N,N-diethylnitrosamine gave nonlinear dose-response curves, but those of N,N-di-n-propylnitrosamine and N,N-di-n butylnitrosamine increased the number of his+ revertants up to a concentration of approx 100 nanomoles (nmol)/plate. At 50 nmol/plate, N-(α-acetoxy)ethyl-N-methylnitrosamine induced 73 his+ revertants/nmol, but the ethyl, propyl, and butyl compounds produced 4, 19, and 26 his+ revertants/nmol, respectively. Dose-response curves for the mutagenicity of N-(acyloxy)-methyl-N-alkylnitrosamine in the absence of S-9 were of the same shape when the alkyl group consisted of a methyl, ethyl, n-propyl, or n-butyl residue. Thus, the mutagenicity of these compounds was inversely related to their half-lives in aqueous media. N-(Acetoxy)methyl-N-tert-butylnitrosamine and a β-acetoxy derivative of N,N-diethylnitrosamine were not mutagenic either in the presence or in the absence of S-9. Thus, α-carbon hydroxylation is one mechanism involved in the metabolic activation of N,N-dialkylnitrosamines. (2
refs)

**78-2707 Effect of Choline Administration on the Toxic
ty of N-Nitrosodimethylamine in Female Rat**
(Eng) Pani, P. (Istituto di Patologia Generale, Via Porcell
09100 Cagliari, Italy); Columbano, A.; Dessi, S.; Porcu, M
Ledda, G. M.; Diaz, G. *Toxicol Appl Pharmacol* 42(3): 61
616; 1977.

The effect of choline administration on the acute toxicity
N-nitrosodimethylamine (DMN) was studied in female rat
A 0.5% aqueous soln of choline was given po at a dos
of 500 mg/kg bid for 3 wk. DMN was injected ip
doses of 40 or 120 mg/kg, and the animals were kil
ed 24 hr or 90 min after intoxication, respectivel
Hepatic necrosis, evaluated by the release of SGP
activity in the serum, was significantly enhanced b
the choline administration. This was confirmed b
morphological observations and by morphometric analyse
of hepatic nuclei. Polysomal disaggregation induced b
DMN was also augmented by choline administration. Cho
line also increased the activity of DMN-demethylas
The results indicate that choline increases DMN toxicit
in female rats, probably through an enhancement
microsomal activities. (14 refs.)

**78-2708 Carcinogenicity and Acute Toxicity of Dime
thylnitrosamine in Rainbow Trout (*Salm*
gairdneri).** (Eng) Grieco, M. P. (R. T. French Co., On
Mustard St., Rochester, NY, 14609); Hendricks,
D.; Scanlan, R. A.; Sinnhuber, R. O.; Pierce, D.
J Natl Cancer Inst 60(5): 1127-1131; 1978.

A chronic dose-response study was made of the ca
cinogenicity of dimethylnitrosamine (DMN) in rainbow trou
(*Salmo gairdneri*), and the results were compared with thos
of a similar study in Porton rats. Trout were also subjecte
to acute exposures to determine the LD50. At the age of
wk, the trout were fed diets containing 0, 3, 50, 200, 400, an
800 ppm DMN for 52 wk, followed by a control, DMN-fr
diet for an additional 26 wk. Thirty trout were sampled
26 and 52 wk, the remainder at 78 wk, to determine tum
incidence. With the six dietary levels, the av total DMN do
per trout was 0, 0.72, 47.8, 45.6, 96.4, and 195.9 mg. At
wk, the respective tumor incidences were 0/60, 0/60, 2/
4/60, 20/60, and 44/60; at 78 wk, these incidences were 0/7
1/75, 14/79, 15/75, 36/73, and 57/63. Thus, the carcinoge
ic response was dose-related. Rats and trout were appr
equal in their sensitivity to DMN carcinogenesis. The LD
after ip injection of DMN was 1,770 mg/kg body wt in t
trout. Relative to the range of 15-50 mg/kg reported for se
eral mammalian species, the trout were resistant to the acu
toxicity of DMN. (11 refs)

78-2709 **Levamisole Is Without Effect in Modifying Chemically Induced Renal Carcinogenesis.** (Eng) Hard, G. C. (Dept. Pathology, Univ. Melbourne Medical Centre, Grattan St., Parkville, Victoria, Australia 3052). *Cancer Lett* 3(5/6): 221-226; 1977.

The effect of levamisole (2,3,5,6-tetrahydro-6-phenylimidazole [2,1-b] thiazole monohydrochloride) on renal tumors induced in female Porton albino Wistar rats by dimethylnitrosamine (DMN: 45 mg/kg ip) was investigated. Levamisole (10 mg/kg) was administered in six sc injections at 3- to 4-day intervals 1-3 wk or 9-12 wk after DMN treatment. Levamisole had no modulating effect on the number of tumor-bearing rats, the incidence of different types of renal tumor, tumor multiplicity, survival time, or tumor size. There was a small number of metastases in both the DMN-only and DMN + levamisole groups. (27 refs)

78-2710 **Effect of a Single Injection of Different Doses of Diethylnitrosamine on the Hepatic Nuclear Fractions in Rats of Various Lines.** (Ukr) Grinchishin, V. P. (Inst. Oncological Problems, Kiev, USSR); Bikoriz, A. I.; Shumilina, V. V. *Dop Akad Nauk Ukr RSR [B]* (12): 1117-1121; 1977.

Diethylnitrosamine (DEN)-induced changes in the hepatic nuclear fraction were studied in random-bred albino rats and Wistar rats. The animals received a single ip injection of DEN: 100 or 250 mg/kg to random-bred rats, 100 mg/kg to Wistar rats. They were sacrified at various time intervals after injection, and the proliferative activity in the hepatic cells was assessed. The ratio of diploid to tetraploid cells in Wistar rats was max (approx 7.5) 12 hr after DEN injection, and it remained increased for at least 3 days. In random-bred rats inoculated with 250 mg/kg, the ratio was increased on day 1 after injection (2.6, compared with 1.92 in rats inoculated with 100 mg/kg and 1.78 in controls), but random-bred rats inoculated with 100 mg/kg showed an increase in the ratio on day 2 after injection (3.6). (2 refs)

78-2711 **In Vitro Demonstration of Mallory Body Formation in Liver Cells from Rats Fed Diethylnitrosamine.** (Eng) Borenfreund, E. (Lab. Cell Biochemistry, Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Bendich, A. *Lab Invest* 38(3): 295-303; 1978.

Epithelioid liver cells were established in culture from rats sacrificed 10-18 wk after administration of the hepatocarcinogen diethylnitrosamine in their drinking water (4 mg/kg/day). After 3 mo in vitro, more than half the cells propagated from rats bearing hepatocellular carcinomas had bean-shaped, acentrically displaced nuclei with large juxtanuclear homogeneous-appearing areas resembling the hyalin or Mallory bodies in the livers of chronic alcoholics. These abnormalities were not seen in the livers of origin, but they were retained in the carcinomas that formed after cultured cells containing such inclusions were injected ip into young Wistar rats or id into nude (thymusless) Swiss mice. Transmission electron microscopy showed that the hyaline bodies in the cultured tumor cells consisted of a disorganized meshwork of filaments. Examination by incubating tumor cells with cytochalasin B and by using antiactin and anti-DNase antisera as indirect immunofluorescence probes also revealed a disturbance in the cytoskeleton. Such an alteration could influence cell movement, metabolism, and transport and could, therefore, be pivotal in the transformation of cells. (46 refs)

78-2712 **Gamma-Glutamyl Transpeptidase: A Positive Marker for Cultured Rat Liver Cells Derived from Putative Premalignant and Malignant Lesions.** (Eng) Laishes, B. A. (McArdle Lab. for Cancer Res., Univ. Wisconsin, Madison, WI, 53706); Ogawa, K.; Roberts, E.; Farber, E. *J Natl Cancer Inst* 60(5): 1009-1016; 1978.

Use of the histochemical localization of γ-glutamyl transpeptidase (γ-GT) as a specific positive marker for rat hepatocytes (H) was assessed in cells derived from: (1) premalignant foci induced by diethylnitrosamine (DEN) and 2-acetylaminofluorene (2-AAF); (2) an early-passage, tumorigenic liver cell line (T50) from a 2-AAF-treated rat; and (3) an established malignant hepatoma cell (HTC) line. High γ-GT levels were located in it from macroscopic, carcinogen-induced lesions at every stage of hepatocarcinogenesis tested. H from normal-looking liver surrounding carcinogen-induced, early lesions were γ-GT-negative. In vitro, γ-GT activity was often localized as spots or bands in the H, and γ-GT-positive (γ-GT+) bile ducts were easily seen. After continuous exposure of rats to 2-AAF or DEN, γ-GT-positive H appeared in vitro only when they were derived from livers containing γ-GT-positive micro- or macroscopic lesions. With early lesions, the relative proportions of γ-GT+ H were greater when the cells were derived from individual lesions rather than from total liver, but they increased in total liver isolates when the lesions increased in size. Grey-white hyperplastic nodules yielded primary cultures containing 29.0%-44.0% γ-GT+ H, with no selective attachment of γ-GT+ H to the cell culture vessels. No γ-GT + H was observed in primary cultures derived from (1) normal adult F344 rats, (2) rats subjected to two-thirds partial hepatectomy, or (3) rats subjected to acute doses of DEN or dimethylnitrosamine. γ-GT activity could not be induced in normal H by exposing them to various carcinogens in vitro, and no γ-GT+ proliferating cells could be isolated from any of the stages of hepatocarcinogenesis except obvious hepatocellular carcinoma. (26 refs)

78-2713 The Carcinogenic Effect of Dimethylnitrosamine in Laboratory Bred European Hamsters (*Cricetus cricetus*). (Eng) Richter-Reichhelm, H. B. (Abteilung fur Experimentelle Pathologie, Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, 3000 Hannover 61, W. Germany); Green, U.; Ketkar, M. B.; Mohr, U. *Cancer Lett* 4(1): 1-4; 1978.

The carcinogenic effect of dimethylnitrosamine (DMN: injected sc once weekly for life at 0.025 or 0.05 the LD_{50}) was studied in laboratory-bred European hamsters, and the data were compared to findings for wild European hamsters. No significant difference could be established between the two dose levels as to survival time and tumor incidence. The first tumor, in the liver, appeared 22 wk after the start of DMN treatment. An almost 100% incidence had developed by the 45th-50th weeks. No differences as to the latency period for these tumors or their localization could be determined between the two treatment groups. Malignant hemangioendotheliomas of the liver and kidney, hepatocellular carcinomas, and cholangiocarcinomas were induced. In contrast to the results obtained with wild European hamsters, a large number of the laboratory-bred females developed ovarian granulosa cell tumors. There was also a greater number of hepatic tumors in laboratory-bred animals. These findings show that differences in maintenance and environment may influence the carcinogenic effect of a given compound. (7 refs)

78-2714 Procarcinogenic Compounds: Problem of Activation in Rapid Testing. (Rus) Belitsky, G. A. (Cancer Res. Center, Moscow, USSR); Khovanova, E. M.; Logvinenko, E. G. *Vestn Akad Med Nauk SSSR* (10): 80-82; 1977.

A new rapid method for screening chemical pro-carcinogens involves the detection of induced somatic mutations in *Drosophila melanogaster* from the cross (female Y/Yx male Wsn^3/Y). These compounds can be activated easily in these organisms to induce a high level of somatic variegation. Several N-nitroso derivatives and their noncarcinogenic analogs were added to the medium. All compounds induced somatic mutations, but the mutagenic activity of the carcinogens was significantly higher than that of their noncarcinogenic analogs. High mutagenic activity was detected not only for the direct carcinogen N-methyl-N′-nitro-N-nitrosoguanidine, but also for the procarcinogens N-nitroso-N,N-dimethylamine and N-nitroso-N,N-diethylamine. 78-2718 Detection of DNA Damage Induced In Vivo Following Exposure of Rats to Carcinogens. (Eng) Petzold, G. L. (Pathology and Toxicology Res. Unit, Upjohn Co., Kalamazoo, MI, 49001); Swenberg, J. A. *Cancer Res* 38(6): 1589-1594; 1978.

A modified alkaline elution assay was used to detect DNA damage in various rat tissues following in vivo exposure of the animals to several classes of carcinogens. Newborn rats were inoculated ip with ^{3}H-thymidine (total, 150 μCi over 3 wk) DNA and then exposed to the carcinogens 1-3 wk later. DNA damage was assessed in the liver, lung, thymus, brain, kidney, stomach, duodenum, colon, bone marrow, and mammary gland. Dimethylnitrosamine (DMN), diethylnitrosamine, 4-nitroquinoline 1-oxide (4-NQO), 2-acetylaminofluorene, N-hydroxyacetylaminofluorene, aflatoxin B_1, 1,2-dimethylhydrazine, azoxymethane, benzidine-HCl, and 7,12-dimethylbenz(a)anthracene induced the greatest extent of DNA damage in target organs for carcinogenicity. Exposure to direct-acting alkylating agents such as N-methyl N′-nitro-N-nitrosoguanidine, N-methyl-N-nitrosourea, N ethyl-N-nitrosourea, methyl methanesulfonate, and ethy methanesulfonate caused significant DNA damage i target and non-target tissues. Dose-related increase in the DNA elution patterns were observed. DNA re pair time, as measured by the return to a normal elu tion pattern, varied from as little as 24 hr for 4-NQ to as long as 7 days for DMN. It is concluded that thi assay is a rapid and reliable method for assessing th ability of a compound to induce DNA damage. (3 refs)

78-2719 Saccharide Alterations in Rat Kidney Associated with Malignant Transformation by Injectio

of Dimethylnitrosamine. (Eng) Whyte, A. (Dept. Pathology, Univ. Cambridge, Tennis Court Road, Cambridge CB2 1QP, England); Loke, Y. W. *Br J Cancer* 37(5): 689-700; 1978.

Cell-surface glycoprotein alterations and saccharide distributions were analyzed in normal rat kidney and renal tumors induced in diet-primed Wistar albino rats by injection of dimethylnitrosamine (DMN: 60 mg/kg ip). (Rats were fed a diet of sucrose and water for the 7 days before DMN injection.) Control and tumor tissue was excised at different periods up to 9 mo after DMN injection and maintained in short-term organ culture in the presence of ^{3}H- or ^{14}C-fucose. The plasma membranes were then isolated, and the isotopic profiles of normal kidney and renal tumor membrane proteins were established, using polyacrylamide gel electrophoresis in dodecyl sulfate. The levels of several fucose-containing glycoproteins of the plasma membranes were altered upon neoplastic transformation: four increased and three decreased. The probable identity of two of these proteins was determined: α-fetoprotein increased whereas neutral endopeptidase decreased in the tumor membranes. Fluorescein-labeled lectin binding by the kidney tissue also was altered upon transformation. The most marked changes were an increase in sialic acid (neuraminidase-sensitive) and galactosamine (*Ricinus communis* agglutinin Type I) in the nuclei of some neoplastic cells and some hyperplastic tubule cells. The nuclear fluorescence of the cells of the DMN-induced renal tumor apparently did not involve the nucleoplasm itself, but was restricted to the nuclear membrane. It may be that alterations of the glycosylated molecules of the nuclear membrane are a common feature of neoplasia. (40 refs)

78-2721 **Differences in the Repair Activity in the Cells of Inbred Mice after Exposure to Chemical Carcinogen 4-Nitroquinoline-1-Oxide.** (Rus) Zasukhina, G. D. (Inst. General Genetics, Moscow, USSR); Sinel'shchikova, T. A.; L'vova, G. N. *Dokl Akad Nauk SSSR* 238(4): 959-962; 1978.

Repair of 4-nitroquinoline -1- oxide-induced DNA breaks was assayed to evaluate the sensitivity of CBA, C57BL/6, and 101/H murine fibroblasts to carcinogen induced damage. There was a max decrease in the mol wt of DNA in the 101/H fibroblasts and a minimal decrease in the CBA fibroblasts. The intensity of DNA degradation was dose-dependent, and the effectiveness of DNA repair was exposure time-dependent. (9 refs)

78-2724 **Ultrastructural Hepatic Changes in Rats after Oral Administration of Ethoxyquin (EMQ).** (Eng) Nafstad, I. (Dept. Pharmacology and Toxicology, Veterinary Coll. Norway, Postboks 8146, Oslo-Dep, Oslo 1, Norway); Skaare, J. U. *Toxicol Lett* 1(5/6): 295-299; 1978.

Ultrastructural changes were determined in the livers of male albino rats after they were administered a single po dose of 500 mg/kg ethoxyquin (EMQ). The rats were sacrificed 3 days later. There was a proliferation of smooth endoplasmic reticulum in the parenchymal cells. Mitochondrial alterations were of minor severity, and they consisted of deformation and derangement of the cristae. Irregular dilation of the perinuclear space was a common occurrence. Alterations in the lining cells appeared to be more severe than those in the parenchymal cells. Dilation of the endoplasmic reticulum and distorted mitochondria were the most striking observations. In some areas, the lining cells were desquamated and fragmented, the cell fragments being intermingled with blood cells in the sinusoids. In another group of rats that had received 150 mg EMQ/liter drinking water throughout an experimental period, no ultrastructural changes were noted. (5 refs)

78-2725 Carcinogenic Effects of Niridazole (an Antischistosomal Drug) on the Kidneys of MRC Rats (Meeting Abstract). (Eng) Bulay, O. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NB 68105); Shubik, P. *Proc Am Assoc Cancer Res* 19: 180; 1978. (no refs)

78-2726 **Production of Adenocarcinomas of the Small Intestines of Wistar Rats Fed Panfuran-S Containing 3-Di(hydroxymethyl)amino -6-(5-nitro -2-**

furylethenyl)-1,2,4-triazine. (Eng) Konishi, Y. (Dept. Oncological Pathology, Cancer Center, Nara Medical Univ., 810 Kashihara, Nara 634, Japan); Denda, A.; Takahashi, S.; Inui, S.; Aoki, Y. *J Natl Cancer Inst* 60(6): 1339-1343; 1978.

When fed to outbred Wistar rats, the antimicrobial agent panfuran-S (PS) produced a high incidence of invasive and metastatic adenocarcinomas of the duodenum and jejunum. Depressed growth and cancer incidence were dependent on the amount of 3-di(hydroxymethyl)amino-6-(5-nitro-2-furylethenyl)-1,2,4-triazine (DHNT) in the contained PS. Duodenal adenocarcinomas were present in 2/18 rats that received 1,750 ppm DHNT in the diet and in 11/19 rats that received 3,500 ppm DHNT. Jejunal adenocarcinomas were present in 10/18 and 16/19 rats that received 1,750 and 3,500 ppm DHNT, respectively, for 35-37 wk. The only other tumors observed were squamous cell papillomas of the forestomach. Histologically, most of the adenocarcinomas appeared tubular or papillary, and they were similar to adenocarcinomas in the human small intestine and also to human intestinal type adenocarcinomas of the stomach. This system provided a useful experimental model for studying the pathogenesis of small intestinal carcinoma. (26 refs)

78-2727 **Nitrofurazone-induced DNA Damage to Tissues of Mice.** (Eng) Olive, P. L. (Radiobiology Section, Johns Hopkins Oncology Center, 601 N. Broadway, Baltimore, MD, 21205). *Chem Biol Interact* 20(3): 323-331; 1978.

Cytotoxicity and DNA damage by nitrofurans has previously been correlated with metabolic reduction of these drugs in vitro. In the present study, nitrofurazone (NF) increased the rate of disappearance of stable ^{3}H-thymidine-labeled DNA from tissues of Swiss albino mice fed 0.1% NF in the diet. A significant loss of labeled DNA occurred within 25 days of the start of the diet in all tissues observed, and the loss was related to the rate of metabolic reduction of NF. A similar correlation was found when another end point for DNA damage was used; NF reduced by mouse tissue slices caused DNA single-strand breaks in cultured mouse L cells incubated in vitro with the tissues. Again, the ability of each tissue to produce toxic NF metabolites determined the amount of DNA damage to the L cells. (23 refs)

78-2728 **Some Effects of Irradiation of Mice in Utero with Tritiated Compounds.** (Eng) Lambert, B. E. (Radiobiol. Dept., Med. Coll. St. Bartholomew's Hosp., London, England); Phipps, M. L. *Curr Top Radiat Res* 12(1): 197-211; 1977.

SAS/4 female mice were exposed in utero to tritiated thymidine (^{3}H-TdR: infused continuously into the mother). For comparison, tritiated water (HTO: via maternal drinking water) was included in the study as a source of internal homogeneous irradiation. In both cases the labeling patterns and subsequent loss of tritium over an extended period were studied. The technique of infusion in unrestrained mice and its application in the production of fully ^{3}H-TdR labeled offspring is described in detail. In HTO-exposed mice, rapid fetal growth did not unduly influence tritium incorporation in utero, and the av organ dose from organically bound tritium was small relative to the dose from tritiated water. The fully labeled mice are being used to study a number of early and late effects, in particular, gonad cell effects and carcinogenesis, following this form of internal irradiation. Some preliminary results are presented. (10 refs)

78-2729 **Comparative Incorporation of Tritium from Tritiated Water Versus Tritiated Thymidine, Uridine or Leucine.** (Eng) Mewissen, D. J. (Dept. Radiology, Univ. Chicago, Chicago, IL); Furedi, M.; Ugarte, A.; Rust, J. H. *Curr Top Radiat Res* 12(1): 225-254; 1977.

Newborn, juvenile, and young adult C57BL mice were inoculated sc or ip with 1 or 10 μCi/g tritiated water (HTO), ^{3}H-thymidine, ^{3}H-leucine, or ^{3}H-uridine. The animals were sacrificed 1, 8, 15, 22, or 29 days posttreatment, and ^{3}H incorporation was assessed in the aqueous fraction and in the organic component of tissues from organs such as the thymus, spleen, lung, liver, brain, and kidney. Following HTO administration, free water ^{3}H activity decreased exponentially with time in all animals. Organically bound (OB) activity was consistently higher in juvenile vs newborn animals and in male vs female adults. After administration of the tritiated precursors, ^{3}H was transferred to the FW pool at a higher rate than the one that occurred following the administration of HTO, which suggested a steady rate of exchange between the OB compartment and the FW pool. RSA values (the ratio of the specific activity of OB ^{3}H to that of aqueous ^{3}H, corrected for relative abundance of hydrogen in either pool) ranged from 0.5 to $<$ 10 after HTO administration, but they decreased a thousandfold after 28 days. Realistic estimates of the internal dose to a radiosensitive nucleus must take into account the age-dependent incorporation of ^{3}H from HTO, as well as the variation between organs. Implications of the results for carcinogenesis from internal irradiation are discussed. (50 refs)

78-2730 **Distribution of Tritiated Compounds (Tritiated Thymidine and Tritiated Water) in the Mother-Fetus System and its Consequences for the Radiotoxic Effect of Tritium.** (Eng) Schreml, W. (Dept. Clinical Phys., Univ. Ulm, D-7900 Ulm-Donau, W. Germany); Fliedner, T. M.; Ohnander, J.; Zipfel, L. *Curr Top Radiat Res* 12(1): 255-277; 1977.

Tritiated thymidine (^{3}H-TdR) and tritiated water (HTO) incorporation and distribution were measured in newborn Wistar rats exposed to the compounds by continuous infusion into pregnant rats from day 9 until term. The tritium levels administered were 0.8 and 1.6 μCi/g/day ^{3}H-TdR and 8 and 16 μCi/g/day HTO. In HTO-exposed animals, tritium activity was distributed homogeneously but ^{3}H-TdR led to the accumulation of DNA-bound and homogeneously distributed tritium. The incorporated activity and the specific activity of DNA from the ovaries, which exhibited an approx 50% reduction in total oocyte number, were used to estimate the dose absorbed by ovarian cell nuclei in both systems. From the absorbed dose, a factor of 3.7 was calculated for the internal relative biological effectiveness of DNA-bound tritium, compared with homogeneously distributed ^{3}H, under the restrictive assumption that the static system at birth reflects the situation during the time of dynamic development of the ovaries, when the toxic effect occurs. The influence of these dynamic factors of changing nuclear size and tritium incorporation during the sensitive period was weighed against the possibility that continuous ^{3}H-TdR infusion during pregnancy might represent a model in which DNA-bound tritium shows a higher effectiveness than homogeneously distributed tritium. (31 refs)

78-2731 **The Genetic and Late Somatic Effects of Chronic Tritium Ingestion in Mice.** (Eng) Carsten, A. L. (Medical Res. Center, Brookhaven Natl. Lab., Upton, Long Island, NY, 11973); Commerford, S. L.; Cronkite, E. P. *Curr Top Radiat Res* 12(1-4): 212-224; 1977.

The long-term somatic and genetic effects of chronic tritium (^{3}H) ingestion were measured in Hale-Stoner-Brookhaven mice. Second-generation animals, who with their parents were maintained on drinking water containing 3 μCi/ml HTO, were bred for dominant lethal testing. The increase in dominant lethal mutations in treated animals compared with tap water controls, was significant at the 1% level. The stem cell content of the bone marrow was measured throughout the lifetime of the animals. A slight reduction in colony-forming units in the bone marrow of treated animals was evident after approx 12 wk, increasing in severity throughout the lifetime of the animals. The distribution of ^{3}H in tissue water protein fractions was determined, and the relative contribution of this ^{3}H to tissue dose was calculated. The differential incorporation into protein fractions was not significant. (13 refs)

78-2732 **Chromosome Aberrations in Human Lymphocytes Exposed to Tritiated Water In Vitro.** (Eng) Bocian, E. (Inst. Nuclear Res., Dorodna 16, 03-195 Warsaw, Poland); Ziemba-Zak, B.; Rosiek, O.; Sablinski, J. *Curr Top Radiat Res* 12(1): 168-181; 1977.

The induction of chromosome aberrations in human peripheral blood lymphocytes by tritiated water (HTO) or 180 kV x-rays was studied in vitro. The lymphocytes were exposed to 1.70-14.36 mCi/ml HTO for 2 hr or to 0.063-0.51 mCi/ml for 53 hr. Chromosomes and chromatid aberrations were scored during the first mitotic division after stimulation with phytohemagglutinin. For analysis of the dose-response relationship, the data were fitted by the least-square method to different models. After acute exposure to tritium β-rays and x-rays, the dicentrics + centric rings and terminal + interstitial deletions gave the best fit to the linear-quadratic function. However, data for these types of aberrations after 53 hr exposure to HTO gave an equally good fit to the linear and linear-quadratic functions. The best description of the dose-response relationship for chromatid aberrations was given by the linear model. The relative biological effectiveness of tritium β-rays compared to 180 kV x-rays was 1.17 ± 0.02. (25 refs)

78-2733 **Tritium Retention in Rat After Administration of Various Doses of Tritiated Water.** (Eng) Radwan, I. (Central Lab. Radiological Protection, Warsaw, Poland); Pietrzak-Flis, Z.; Jaworowski, Z. *Curr Top Radiat Res* 12(1): 278-290; 1977.

Four groups of hooded inbred rats were inoculated sc with tritiated water (HTO) at the following doses: Group I (controls), 1.8 μCi/g; Group II, 25 μCi/g; Group 3, 50 μCi/g; Group 4, 115 μCi/g. Samples of liver, lung, skin, muscle, and intestinal tissue were collected at 1-, 3-, and 5-day intervals over a 21-day period. Free-water and tissue-bound HTO concentrations were determined, and the biological half-life (Tb) of tritium was calculated by the least-squares method. The Tb of free-water tritium varied from 3.5 days in kidney to 4.8 days in muscle in Group I animals; the values were slightly lower in the higher-dose groups. The retention of tissue-bound tritium varied in each group, with Tb values ranging from 10.3 days in the large intestine to 85.0 days in the muscle of control rats. The values decreased significantly at higher HTO doses. This result is the opposite of the effect observed after external x-ray irradiation at the same dose level. (7 refs)

78-2734 **The Early Retention of Monomeric ^{237}Pu(IV)- and ^{239}Pu(IV)-Citrate in C57BL/Do and BALB/cJ Mice.** (Eng) Smith, J. M. (Radiobiology Lab., Univ. Utah Coll. Medicine, Salt Lake City, UT, 84112); Taylor, G. N.; Mays, C. W.; Atherton, D. R. *Radiat Res* 73(3): 502-509; 1978.

The early retention (6 hr to 28 days postinjection) of plutonium(IV) citrate was followed in C57BL/Do and BALB/cJ mice. As a tracer, the photon-emitting nuclide, ^{237}Pu, was mixed with α-emitting ^{239}Pu, so that Pu retention could be determined by standard NaI(Tl) crystal scintillation spectroscopy. Mice were inoculated ip with 0.3-0.5 μCi ^{239}Pu/kg containing 0.5-1.0 μCi ^{237}Pu/kg. The BALB/cJ mice showed essentially the same early retention of Pu as the C57BL/Do mice. By 12 hr, the females had excreted more than twice as much of the injected Pu as the males. Since these and previous studies establish that the sex difference for Pu retention in mice is reproducible and exists in at least two strains, further experiments were conducted. Six male and six female C57BL/Do were gonadectomized (GD) 3-4 wk prior to injection, and 10 male BALB/Cj mice were GD 2 wk prior to injection. Retention of Pu by GD females did not differ significantly from that of intact females, but Pu retention by GD males resembled that of the females. When ^{237}Pu(IV)- and ^{239}Pu(IV)-citrate was given iv to intact male and female BALB/cJ mice, the sex difference in Pu retention was less pronounced. Physiological factors, other than specific protein binding, may be responsible for the sex difference. However, if the transport of Pu out of the peritoneal cavity and its ultimate distribution and retention are determined in some way by cellular activity or by specific protein binding, either path may be under the influence of sex hormones. (17 refs)

78-2735 **Blood Lymphocyte Chromosome Aberrations in Plutonium Workers (Meeting Abstract).** (Eng Brandom, W. (Univ. Denver, Denver, CO, 80210); Bloom A.; Archer, P.; Bistline, R. *Mutat Res* 53(1): 79; 1978. (no refs)

78-2736 **Gynecologic Morbidity in Women Exposed Occupationally to Radioactive Substances.** (Rus Muratova, R. M. (All-Union Res. Inst. Social Hygiene and Organization of Health Care, Moscow, USSR); Chusova, V N. *Med Radiol (Mosk)* (7): 52-55; 1978.

Gynecologic morbidity was studied in a group of 100 women who had been exposed occupationally to radioactive substances (isotopes of radium, thorium). Patients wer divided into two groups: Group 1 included 23 women who received a total of 100-400 roentgens-equivalent-man (rem) of external irradiation, and Group 2 included 77 women who received total of 30-100 rem. The overall incidence of gynecologic diseases in Groups 1 and 2 was 73.8% and 67.1%, respectively; 12.6% of the women in Group 1 and 7.7% in Group 2 had uterine myomas. Several years prior to the development of myoma, most of the patients had transient hypoestrogenemia (8.97-24.13 μg/day). (14 refs)

78-2737 **Interactions Between Polonium-210 α-Radiation, Benzo(a)pyrene, and 0.9% NaCl Solution Instillations in the Induction of Experimental Lung Cancer.** (Eng) Little, J. B. (Dept. Physiology, Harvard Sch. Public Health, Boston, MA, 02115); McGandy, R. B.; Kennedy, A. R. *Cancer Res* 38(7): 1929-1935; 1978.

Benzo(a)pyrene (BP) and ^{210}Po were administered both simultaneously and sequentially by intratracheal instillations to Syrian golden hamsters in experiments designed to identify any synergistic interactions (SI) between these carcinogens. There was significant SI when BP exposure followed 5 mo after ^{210}Po exposure and the effects were additive after simultaneous administration. The implications of these findings in terms of the interaction between α-radiation and cigarette smoke in human populations are discussed. (28 refs)

78-2738 **Changing Levels of UV Light and Carcinogen-Induced Unscheduled DNA Synthesis in Mouse Oocytes During Meiotic Maturation.** (Eng) Brazill, J. L. (Dept. Zoology, Univ. Toronto, Ontario M5S 1A1, Canada); Masui, Y. *Exp Cell Res* 112(1): 121-125; 1978.

Mouse oocytes were exposed in vitro to three DNA-damaging agents at the germinal vesicle (GV), metaphase I (MI), or metaphase II (M II) stage of meiotic maturation and then labelled with ^{3}H-thymidine for 2.0 hr. The levels of unscheduled DNA synthesis induced in the oocytes at the different stages of maturation by the agents were ranked in the following order: GV > M-I = M-II when exposed to UV light; GV > M-I > M-II when exposed to 4-nitroquinoline-1-oxide (4-NQO); GV = M-I = M-II when exposed to methyl methanesulfonate (MMS). When the oocytes were exposed to UV light or 4-NQO at the M-II stage, the unscheduled DNA synthesis levels in the polar bodies were considerably lower than those in the oocytes. However, MMS exposure at the M-II stage resulted in the same levels of unscheduled DNA synthesis in the polar bodies and the oocytes. Factors that may account for both the variable levels of unscheduled DNA synthesis at the different stages, as well as the differential response of the oocytes and the polar bodies, are discussed. (15 refs)

78-2739 **Ultraviolet Light-induced Sister Chromatid Exchanges in Xeroderma Pigmentosum and in Cockayne's Syndrome Lymphocyte Cell Lines.** (Eng) Cheng, W. S. (Medicine Branch, NCI, NIH, Bethesda, MD, 20014); Tarone, R. E.; Andrews, A. D.; Whang-Peng, J. S.; Robbins, J. H. *Cancer Res* 38(6): 1601-1609; 1978.

Sister chromatid exchanges (SCE) were studied in lymphocyte cell lines derived from 11 patients with xeroderma pigmentosum (XP; representing all 6 forms of XP) and 2 patients with Cockayne's syndrome (CS). XP patients have DNA repair defects and develop numerous tumors on sun-exposed skin; CS patients do not develop such tumors, and the cause of the sensitivity of their cells to UV light is not known. Reciprocal SCE were evaluated by fluorescence microscopy following staining of the chromosomes with the bisbenzimidazole dye 33258 Hoechst after the cells had passed through two phases of DNA synthesis in the presence of 5-bromodeoxyuridine. In the absence of UV irradiation, XP and CS cells had the same frequency of spontaneous SCE as did normal cells. UV irradiation resulted in significant increases in the SCE of normal, XP, and CS cells. The number of UV-induced SCE in an XP variant's cells was not greater than the number in normal cells. The number of UV-induced SCE in XP complementation group B and E cells and in the CS cells was higher than that in normal cells, but the difference was not significant. All XP complementation group A, C, and D cells tested had significantly greater numbers of UV-induced SCE than did normal cells. There were significant differences in the number of UV-induced SCE among cells from unrelated XP group C patients, but cells from three XP group C siblings had almost identical UV-induced responses. In normal and XP cells, there was a significantly greater number of spontaneous and UV-induced SCE in the longer chromosomes than in the shorter chromosomes. (47 refs)

78-2743 **Mechanisms of the Carcinogenic Effect of UV Radiation.** (Ita) Feo, F. (No affiliation given). *Minerva Med* 69(12): 770-773; 1978.

Epidemiological evidence shows that there is a carcinogenic effect of UV radiation on exposed skin areas. According to a recent hypothesis, malignant transformation is initiated during the repair of the UV-damaged DNA and not by the DNA damage itself. (no refs)

78-2745 **Sister Chromatid Exchanges in Lymphocytes from Psoriasis Patients Treated with 8-Methoxypsoralen and Longwave Ultraviolet Light.** (Eng) Lambert, B. (Dept. Clinical Genetics, Karolinska sjukhuset, S-104 01 Stockholm 60, Sweden); Morad, M.; Bredberg, A.; Swanbeck, G.; Thyresson-Hok, M. *Acta Derm Venereol (Stockh)* 58(1): 13-16; 1978.

The frequency of sister chromatid exchanges (SCE) was determined in the peripheral blood lymphocytes of 14 psoriasis patients (7 men, 7 women aged 14-63 yr) before, during, and after treatment. Each patient received 0.6 mg/kg 8-methoxypsoralen (8-MOP) po and, 2.0-2.5 hr later, longwave UV light (UVA) radiation using black light fluorescent lamps with a spectral max at 360 nanometers. Irradiation usually lasted 20 min, during which time a total dose of approx 3 joules/cm^2 was delivered. The treatment was given 5 days per week for 3-30 wk, depending on the healing progress. The frequency of SCE was approx the same before and after treatment. In another part of the experiment, in vitro UVA irradiation of cells from patients who had taken 8-MOP 2.0-2.5 hr before blood sampling increased SCE frequency: a dose of 1.8 joules/cm^2 increased the av number of SCE/cell by 24% and 3.6 joules/cm^2 increased it by 54%, compared with nonirradiated controls. There was no increase after systemic 8-MOP tretament alone or after UVA irradiation alone. Thus, po 8-MOP and UVA increase the number of SCE in peripheral lymphocytes in vitro, but clinical UVA skin irradiation in vivo does not produce this effect. It is possible that the accumulated UVA dose in circulating lymphocytes is not large enough to produce SCE or that the DNA damage caused by this treatment is repaired during the treatment intervals. Three cellular systems differing in DNA repair activity were investigated: human diploid cells and cells infected by leukosis virus; commercial and leukosis-free chick embryo cells; and primary and established Syrian hamster kidney (SHK) cells. At 24 hr post-UV irradiation, no excision of thymine dimers in the DNA was observed in the virus-infected human cells, commercial chick embryo cells latently infected with avian leukosis virus, or the two established SHK lines. Nitrosoguanidine significantly enhanced the number of virus-induced chromosome aberrations in virus-infected diploid cells, and, in contrast to γ irradiation, it induced unrepairable DNA damage. In the infected chick embryo cells, DNA repair was observed after γ irradiation but not after ethyleneimine treatment. This chemical also increased the number of chromosome abberations. Repression of repair capacity and an enhancement of chromosome aberrations may be an initial mechanism in the malignant transformation of a normal cell. (no refs)

78-2750 **Frequent Appearance of Radiation-induced Transformation in Junctional Areas of Colonies.** (Eng) Okada, Y. S. (Div. Physiology and Pathology, Natl. Inst. Radiological Sciences, Anagawa 4-9-1, Chiba 280, Japan); Watanabe, I. *Gann* 69(1): 91-93; 1978.

Transformation induction was studied in mouse embryo 10T-1/2 cells that had been x-irradiated with 600 R. Following irradiation, at least three different types of morphologically altered foci were noted: Type 1 consisted of tightly packed cells, but there was no other deviation from normal morphology; Type 2 appeared as a focus of cells piled into opaque multilayers; Type 3 consisted of densely piled, multilayered cells criss-crossed by arrays of densely stained cells. Since Types 2 and 3 have been shown to form malignant tumors in syngeneic mice, they were studied further. The morphology of these cells in the interior of a colony was almost uniform. Phenotypic changes were noted only when two or three colonies contacted each other. The phenotypic changes included the appearance of morphologically altered cells, the formation of giant cells, and the development of transformed cells. These altered cells were also characterized by a change in cytoplasmic affinity to May-Grunwald and Giemsa staining. The transformation frequency was $< 10^{-2}$; the frequency of induction of giant cells was apparently higher than that of transformed foci. The phenotypically changed cells appeared to be induced by overlapping of the cells of two developing colonies and by interaction between the cells. Contact between colonies is suggested to be an important factor in radiation-induced transformation. (6 refs)

78-2751 **Induction of Colonic Adenocarcinoma in the Rat by X-Irradiation.** (Eng) Denman, D. L. (Radiation Res. Lab., 14 Medical Labs., Univ. Iowa, Iowa City, IA, 52242); Kirchner, F. R.; Osborne, J. W. *Cancer Res* 38(7): 1899-1905; 1978.

A procedure for the in situ irradiation of the rat descending colon was developed to study how the level of x-ray exposure affects the incidence of colonic neoplasms. Only the descending colons of the rats were irradiated with a collimated x-ray beam. Ninety male Holtzman rats were divided into six exposure groups of 15 animals each. In the first group, the colon was exposed to 2,500 R: for each successive group, the exposure was increased by 1,000-R increments through 6,500 R. The sixth group was sham-irradiated. Animals in each of the irradiated groups developed mucoid adenocarcinomas, with the highest incidence (47%) being observed in the 4,500-R group. Histopathologically, the tumors were well-differentiated adenocarcinomas that closely resembled human colon adenocarcinomas. One of the animals with multiple primary tumors developed pulmonary metastases. During histological studies of the irradiated colons from animals not displaying grossly visible tumors, many areas of pathological bone formation were noted. These foci of heterotopic ossification were present in many of the irradiated colons regardless of whether cancer had developed. No reports of radiation-induced bone formation in the colon could be found in the literature. (16 refs)

78-2752 **Radiation Induced Ovarian Pathogenesis in the Progeny of X-irradiated Female Mice.** (Eng) Palayoor, T. (Embryology Div., Cancer Res. Inst., Bombay 400 012, India); Batra, V. K.; Batra, B. K. *Indian J Exp Biol* 15(3): 163-167; 1978.

Female C57BL ICRC mice were given a whole-body dose of 300 R x-rays and mated with unexposed litter mates. The descendants resulting from several generations of inbreeding had decreased gonadotropic activity. Offspring from the 16th generation onward were exposed at weaning to 400 R γ-rays and autopsied 2.5-3.5 mo later. Adenomatous growths observed in the ovaries of mice sacrificed 3.5 mo after irradiation were not considered tumors, but their resemblance in structure and possible histogenesis to neoplastic developments in irradiated mouse ovaries reported by others was obvious. No adenomatous growths were observed in the ovaries of control animals similarly irradiated, but initial stages of change were noted. The reduction of the latency period can be considered a significant alteration in the ovarian response of the treated progeny to ionizing radiation. This reduction may reflect the inherent qualities of ovarian cells to react to the hormonal stimulus available (in this case, decreased pituitary gonadotropic potency) more intensely than the cellular components of the control ovaries. 78-2755 **Myeloid Leukaemia in X-ray Irradiated CBA Mice.** (Eng) Major, I. R. (Radiobiology Unit, Medical Res. Council, Harwell, Didcot, Oxon, England); Mole, R. H. *Nature* 272(5652): 455-456; 1978.

The development of myeloid leukemia (ML) was studied in male CBA mice given a single, brief, whole-body x-ray exposure. The dose-response relationship was highly curvilinear, and the optimum dose for ML induction was in the region 150-300 rads. Larger doses resulted in a substantial and significant reduction in leukemia frequency. In a further study, ML frequency in mice exposed to 300 rads was markedly reduced (or postponed) by a further 600-rad dose given 1, 4, 16, or 32 wk later. The results support the hypothesis that the dose-dependent reduction of leukemia in this strain is the result of competition between two concomitant radiation effects: malignant transformation and cellular inactivation (loss of the ability to undergo sequential cell division). 78-2756 **Malignant Transformation in Cultured Hamster Embryo Cells Produced by X-Rays, 430-keV Monoenergetic Neutrons, and Heavy Ions.** (Eng) Borek, C. (Dept. Radiology, Coll. Physicians and Surgeons, Columbia Univ., New York, NY, 10032); Hall, E. J.; Rossi, H. H. *Cancer Res* 38(9): 2997-3005; 1978.

The efficiency of x-rays (1-600 rads), 430-kiloelectron volt (keV) monoenergetic neutrons (0.1-150 rads), and argon ions (429 million electron volts/atomic mass unit) in producing tumors in short-term cultures of golden hamster embryo cells was determined. The transformation frequency per surviving cell for neutrons reached a higher max value than that for x-rays. When the data were expressed as the number of transformations per initial cells at risk, the two dose-response curves rose to essentially the same peak value. Thus the max carcinogenic potential of the two types of radiation is the same. The relative biological effectiveness of neutrons relative to x-rays was not greatly different whether killing or transformation was the end point scored. Studies of the biological properties of the malignant transformed cells indicated no qualitative difference in those transformed by neutrons compared with those transformed by x-rays. Argon ions were much more effective in producing transformations than x-rays, and they were similar in effectiveness to 430-keV neutrons. (36 refs.)

78-2759 **Gastric Stump Cancer: Statistical Evaluation.** (Eng) Cheli, R. (Divisione de Gastroenterologia, Ospedali Civili di Genova, Ospedale Generale Regionale, Viale Benedetto XV, 16132 Genoa, Italy); Molinari, F.; Santi, L.; Ciancamerla, G.; Puntoni, R. *Rend Gastroenterol* 9(3): 169-172; 1978.

The incidence of gastric stump cancer was determined in 180 patients who underwent resection of a gastric ulcer and 337 patients who underwent resection of a duodenal ulcer. Seven of the former and nine of the latter group died of stump cancer; the interval between surgery and death was 13-16 yr. Comparison with a control group indicated that the risk of gastric cancer was significantly higher in the ulcer patients. The reason for this higher risk is not known. (23 refs)

78-2760 **Malignant Astrocytoma Following Radiotherapy of a Craniopharyngioma. Case Report.** (Eng) Sogg, R. L. (Div. Ophthalmology, Stanford Univ. Medical Center, Stanford, CA, 94305); Donaldson, S. S.; Yorke, C. H. *J Neurosurg* 48(4): 622-627; 1978.

A malignant astrocytoma developed in the right temporal lobe of a 14-yr-old girl 5 yr after she had received 6,007 rads to the suprasellar region for a craniopharyngioma. Superimposition of isodose curves from the original irradiation on the site of the glioma showed that it had received 80%-95% of the original 6,007 rads. There was no microscopic connection between the craniopharyngioma and the glioma. (16 refs)

78-2761 **Development of Highly Differentiated Thyroid Carcinomas.** (Rus) Valdina, E. A. (Dept. Pulmonary and Mediastinal Tumors, N. N. Petrov Scientific Res. Inst. Oncology, Leningrad, USSR); Puchkov, Yu. G. *Vopr Onkol* 23(11): 23-29; 1977.

To verify the hypothesis that highly differentiated carcinomas can undergo anaplastic transformation (especially after irradiation), the case histories of 83 patients subjected to repeated surgery for highly differentiated carcinoma of the thyroid are reviewed. The interval between the first and second surgery ranged from 2 to 15 yr, and 30 patients had received radiotherapy before or after the first surgery. Although the morphological diagnosis of the tumor was reconsidered in 51 patients, none of them showed signs of anaplasia. In a group of 11 patients in whom the interval between surgeries ranged from 8 to 15 yr, both the recurrent tumor and the regional and hematogenic metastases retained the features of a highly differentiated carcinoma. (15 refs)

78-2763 **The Effect of Different Mineral Dusts on the Mechanism of Phagocytosis: A Scanning Electron Microscope Study.** (Eng) Miller, K. (Dept. Immunology, Natl. Res. Inst. Occupational Diseases, South African Medical Res. Council, Johannesburg 2000, S. Africa); Handfield, R. I.; Kagan, E. *Environ Res* 15(1): 139-154; 1978.

A scanning electron microscopic study was made of the ability of male Wistar rat alveolar macrophages to phagocytize crocidolite asbestos fibers (≥ 20 μm or ≤ 5 μm in length) and quartz particles (1-3 μm in diameter). Both short and long asbestos fibers were firmly attached to the macrophages after 4 min. Attachment of the short fibers occurred without any extensive spreading of pseudopodia or development of filopodia. After 20 min, phagocytosis of all the fibers was complete. With long fibers, many macrophages developed large flattened pseudopodia, and the fibers were attached, along their long axis, to the pseudopodia by small cytoplasmic tendrils. Phagocytosis of one or more fibers did not prevent the cell from further active phagocytosis. After 30 min of incubation, long fibers were still present in the culture, and macrophages were still attempting to phagocytose them. Quartz particles, however, were phagocytosed within 2-4 min. The macrophages developed long tenuous filopodia to which the quartz particles were attached. These differences in phagocytosis could be the result of the different physicochemical properties of the fibers. The recognition and attachment of the fibers could have some bearing on the role of the macrophage in the pathogenesis of dust disease. (11 refs)

78-2764 **Ferruginous Bodies in Sputa of Former Asbestos Workers.** (Eng) Farley, M. L. (Tyler Asbestos Workers Program, Texas Chest Foundation, East Texas Chest Hosp., Tyler, TX); Greenberg, S. D.; Shuford, E. H.; Hurst, G. A.; Spivey, C. G.; Christianson, C. S. *Acta Cytol (Baltimore)* 21(5): 693-700; 1977.

The occurrence of ferruginous bodies in the sputa of 628 former asbestos workers and 138 controls was determined, and the findings were related to age, cigarette smoking history, cellular atypia, time since last occupational exposure, and length of occupational exposure. No ferruginous bodies were detected in sputum specimens from controls, but they were detected in 224 former workers. One worker with only 1 day of exposure 10 yr previously had one body in 1/4 sputum specimens. Generally, the number of bodies was related to the age of the worker and length of exposure. However, study of the significance of each of these factors indicated that only length of exposure and number of ferruginous bodies were related by an increasing logarithmic function. No significant association was found between these bodies and age, smoking history, degree of cellular epithelial atypia, or time since last exposure. It is concluded that ferruginous bodies in the sputa are evidence of probable significant occupational exposure to asbestos dust and that routine cytopathology procedures are sufficient for their detection. (30 refs)

78-2765 **Morphological Changes in Sc Connective Tissue of Rats after Implantation of Polymers Used in Stomatology.** (Rus) Zabezhinsky, M. A. (Lab. Chemical Carcinogens, N. N. Petrov Scientific Res. Inst. Oncology, Leningrad, USSR); Pliss, G. B.; Eliseev, V. V.; Bobin, E. Yu.; Shteingart, M. Z. *Vopr Onkol* 24(1): 94-95; 1978.

To evaluate the possible carcinogenic effect of the polymers used in stomatology, the polymer AKR-15 (Ethakril) or its analog were implanted sc in random-bred albino rats. The polymers were in the form of a plate or a powder (500 mg). Implantation of plastic plates resulted in the development of tumoral encapsulated nodes in 10/26 rats implanted with AKR-15 and 7/14 rats implanted with its analog (av latent periods were 16.5 and 15 mo, respectively). Rats implanted with powder were tumor-free. (2 refs)

78-2766 **Reverse Transcriptase of RNA Tumor Viruses. V. In Vitro Proteolysis of Reverse Transcriptase from Avian Myeloblastosis Virus and Isolation of a Polypeptide Manifesting Only RNase H Activity.** (Eng) Lai, M. T. (Tumor Virology Lab., Salk Inst., San Diego, CA, 92112); Verma, I. M. *J Virol* 25(2): 652-663; 1978.

Purified avian myeloblastosis virus reverse transcriptase contains two structurally related subunits. The larger subunit, β (mol wt, 95,000), was converted in vitro by chymotrypsin into a polypeptide with a mol wt of 63,000. This polypeptide was indistinguishable from the smaller subunit, α (mol wt 65,000), in its chromatographic behavior on a phosphocellulose column and in its tryptic peptide composition. A 32,000-mol-wt polypeptide (fragment B) generated during proteolysis was composed of tryptic peptides unique to β, and it appeared to be derived from the portion of the subunit that was cleaved during the conversion of the latter into α. Upon continued proteolysis, a 24,000-mol-wt peptide (fragment A) was generated. This polypeptide manifested only RNase H activity and shared common amino acid sequences with the β and α subunits. Fragments A and B did not share any amino acid sequence homology. (45 refs)

78-2767 **Anti-tumor Virus Activity of Copper-binding Drugs.** (Eng) Levinson, W. (Dept. Microbiology, Univ. California at San Francisco, San Francisco, CA 94143); Mikelens, P.; Jackson, J.; Kaska, W. *Adv Exp Med Biol* 91: 161-178; 1977.

Several Cu-binding ligands can inhibit the RNA-dependent DNA polymerase activity of Rous sarcoma virus (RSV) and inactivate the ability of this virus to transform chicken embryo cells. Compounds effective as free ligands and as Cu complexes in inhibiting both RNA-dependent DNA polymerase activity and transforming ability include N-methylisatin β-thiosemicarbazone, 2-pyridine thiosemicarbazone, and 8-hydroquinoline and its 5-chloro and 7-iodo derivatives. Kethoxal bis(thiosemicarbazone), thiosemicarbazide, and dithizone were less active as free ligands than as preformed complexes and isoquinoline 1-formyl thiosemicarbazone was active as a free ligand. Isonicotinic acid hydrazide was active only in complex form. O-Phenanthroline and aurintricarboxylic acid inhibited the polymerase but failed to inactivate transforming ability except at high concentrations. Some Cu-binding ligands had no effect on either parameter. Thus, there is no simple relationship between the antiviral activity of Cu-binding ligands and their nucleic acid-binding activity. However, the biological importance of thiosemicarbazone-Cu complex binding to nucleic acids is supported by the observation that treatment of intact RSV virions with the complex causes 70S RNA to sediment abnormally in centrifugation analyses. (46 refs.)

78-2768 **Polyadenylated RNA Molecules and Polyribosomes in Tumours of Chemical and Viral Origin.** (Eng) Shaposhnikov, J. D. (Lab. Biochemistry, Prof. N. N. Petrov Res. Inst. Oncology, 188646 Leningrad, USSR); Ratovitski, E. A. *Int J Cancer* 21(3): 395-399; 1978.

The distribution of polyadenosine [poly(A)]-enriched messenger RNA in the nuclei, mitochondria, and free and membrane-bound polyribosomes from normal C3HA mouse and Syrian hamster livers and normal chicken fibroblasts was compared with that in the corresponding subcellular fractions in the transplantable, chemically induced MD hepatoma and in non-virus-producer hamster and virus-producer avian (chicken) Rous sarcomas. The amount of poly(A)-RNA was higher in the nuclei, mitochondria, and membrane-bound polysomes of the tumor cells than in normal cells. In the free polysomes of the hepatoma and the hamster Rous sarcoma, the poly(A)-RNA content was not changed significantly, but the free polysomes of avian Rous sarcoma contained less poly(A)-RNA than normal chicken fibroblasts. Differences between free and membrane-bound polysomes can be related to changes in the amount of ribosomal RNA. A study of the comparative distribution of free, membrane-bound, and mitochondria-associated polysomes in normal and transformed cells indicated that the relative content of free polysomes was increased in transformed cells. Therefore, the amount of polysome associated with various membranous structures was decreased. The amount of mitochondria-associated polysomes per milligram of mitochondrial protein was reduced in the hepatoma, almost the same in the hamster sarcoma, and significantly increased in the chicken sarcoma compared to their normal cell counterparts. It is concluded that in carcinogen-induced, virus-producing, and non-virus-producing tumors, similar changes occur in the subcellular distribution of polyribosomes and poly(A)-containing RNA. (32 refs)

78-2769 **The Size and Genetic Composition of Virus-specific RNAs in the Cytoplasm of Cells Producing Avian Sarcoma-Leukosis Viruses.** (Eng) Weiss, S. R. (Dept. Microbiology, Univ. California, San Francisco, CA 94143); Varmus, H. E.; Bishop, J. M. *Cell* 12(4): 983-992; 1977.

The major species of stable virus-specific RNA's were identified and characterized in chicken embryo fibroblasts productively infected with both nondefective and defective strains of avian sarcoma virus (ASV). Radioactive DNA's (cDNA) complementary to defined portions of the ASV genome were used to characterize the virus-specific RNA molecules. The cytoplasm of the cells producing nondefective ASV contained three species of polyadenylated virus-specific RNA. These species may serve as messengers for the synthesis of viral proteins. The largest species (3.3 x 10^6 daltons) encodes all four viral genes and is probably identical with the viral genome. A second species (1.8 x 10^6 daltons) encodes the $3'$ half of the viral genome, including *env*, *src*, and a genetically silent region known as "c". The three species of virus-specific RNA contain nucleotide sequences at least partially homologous to a sequence of 101 nucleotides found at the extreme $5'$ end of the ASV genome. The size and genetic composition of virus-specific RNA's in cells producing defective deletion mutants reflected the nature of the deletion. It is hypothesized that 3/4 viral genes (*gag*, *env*, and *src*) are translated from distinct messenger RNA's that contain the expressed gene at the $5'$ end. The remaining gene, *pol*, may be expressed by the synthesis and subsequent processing of a polyprotein that contains the products of both *gag* and *pol*. (49 refs.)

78-2770 **Uninfected Avian Cells Contain RNA Related to the Transforming Gene of Avian Sarcoma Viruses.** (Eng) Spector, D. H. (Dept. Microbiology, Univ. California, San Francisco, CA, 94143); Smith, K.; Padgett, T.; McCombe, P.; Roulland-Dussoix, D.; Moscovici, C.; Varmus, H. E.; Bishop, J. M. *Cell* 13(2): 371-379; 1978.

The DNA of uninfected avian cells contains nucleotide sequences (*sarc*) related to the transforming gene (*src*) of avian sarcoma virus. In the present study, *sarc* was transcribed into RNA in a variety of normal and neoplastic avian cells and tissues, including cultured embryonic fibroblasts, normal embryos, normal adult tissues, methylcholanthrene-induced fibrosarcomas, and cells explanted from these tumors into continuous culture. Since RNA was not transcribed from the genes for globin and ovalbumin in embryonic avian fibroblasts, the presence of *sarc* RNA in normal cells cannot be attributed to a low constitutive level of transcription from all cellular genes. *Sarc* RNA levels were similar in normal and neoplastic cells, in embryos at all stages of development, and in both logarithmically growing and fully quiescent fibroblasts. Synthesis of *sarc* RNA in chicken cells was coordinated with the expression of endogenous retrovirus genes. This confirms other evidence that *sarc* is not linked to an endogenous viral genome. Although *sarc* is part of messenger RNA in normal and neoplastic avian cells, it is not implicated in normal cellular growth, embryogenesis, or chemical carcinogenesis. (28 refs)

78-2771 **Intracellular Precursors to the Major Glycoprotein of Avian Oncoviruses in Chicken Embryo Fibroblasts.** (Eng) Buchhagen, D. L. (Sidney Farber Cancer Inst., Boston, MA, 02115); Hanafusa, H. *J Virol* 25(3): 845-851; 1978.

The identification of a 96,000-dalton glycoprotein, p(96), is reported. It was present in cell extracts from gs-chf-chicken embryo fibroblasts infected with Rous-associated virus-2 subgroup B (RAV-2) and the Schmidt-Ruppin strain of Rous sarcoma virus subgroup A (SR-RSV-A), as well as from uninfected gsLchf+ (HE) cell extracts. It was not found in cell extracts from uninfected gs-chf- or gs+chf+ (HH) cells or from gs-chf-cells infected with envelope-deficient Bryan high-titer Rous sarcoma virus. Immunoprecipitation, kinetic, and biochemical data indicated that this polyprotein was a precursor to gp85. A second polyprotein of 80,000 daltons, p(80), was also present in the RAV-2- and SR-RSV-A-infected gs-chf- cells. This second polyprotein contained less carbohydrate than p(96), and kinetic and biochemical data indicated that p(80) may be an immature form of p(96). (22 refs)

78-2773 **Cytoplasmic Vacuoles of Rous Virus Transformed Cells Are Organelles Involved in Cation Uptake.** (Eng) Bader, J. P. (NCI, NIH, Bethesda, MD, 20014); Brown, N. R. *J Gen Virol* 38(3): 471-481; 1978.

Cytoplasmic vacuoles induced during the transformation of chick embryo cells by Bryan strain of Rous sarcoma virus (RSV-BH) were studied using neutral red (NR), a cationic dye. Both the rate of uptake and the accumulation of NR were greater in RSV-BH-transformed cells than in nontransformed cells. However, uptake was greater in vacuolated than in nonvacuolated cells, whether or not they were transformed. The NR was incorporated into preexisting vacuoles in the absence of cytoplasmic staining, suggesting the existence of direct channels from the cell surface to the vacuoles. Other low-mol-wt cationic dyes could also be incorporated into vacuoles, but those with branched structures or cationic wts > 330 were excluded; no anionic dyes were incorporated. In experiments with the mutant RSV-BH-Ta, which induces temperature-dependent vacuolization, vacuoles developed at different rates and at various morphologies with different cations, following a shift to the vacuole-permissive temperature. Vacuoles that had formed in the presence of K^+, Rb^+, tris+, and choline+ failed to disappear when cells were incubated at a temperature sufficient to revert vacuoles formed in Na+-containing medium. No short-term effects of Cl^- replacements (Br^-, I^-, or SO_4^{2-}) on vacuolization or reversal were observed. These findings suggest that the vacuoles are organelles involved in cation uptake. In transformed cells, the increased Na+ content (most common cation) in the vacuoles could affect the extent or specificity of transcription and be responsible for the failure of these cells to respond to regulatory mechanisms. (11 refs)

78-2775 **Autoradiographic Studies of Proviral DNA Synthesis in Enucleated Chick Embryo Fibroblasts Infected with Avian Sarcoma Virus.** (Jpn) Tanaka, T. (Dept. Biochemistry, Cancer Inst. Okayama Univ., Shikadacho, Okayama 700, Japan). *Okayama Igaku Zasshi* 89(9/10): 1177-1186; 1977.

After infection of susceptible cells with RNA tumor viruses, viral RNA is reversibly transcribed into proviral DNA. To determine the site of proviral DNA synthesis, chick embryo fibroblasts (CEF) were enucleated by centrifugation in the presence of cytochalasin B, and the enucleated CEF (cytoplasts) were infected with the B77 strain of avian sarcoma virus (B77-ASV). ^{3}H-thymidine incorporation into cytoplast DNA was investigated by autoradiography. Photopositive grains were observed in cytoplasts infected with B77-ASV, but not in mock-infected cytoplasts. The photopositive grains in the B77-ASV-infected cytoplasts disappeared almost completely after DNase I treatment. N-Demethylrifampicin, a specific inhibitor of reverse transcriptase, inhibited the appearance of photopositive grains. When ultrathin sections of the infected cytoplasts were studied by electron microscope autoradiography, the photopositive grains appeared in the cytoplasm without relation to mitochondria. These results indicate that proviral DNA synthesis is initiated in the cytoplasm of B77-ASV-infected CEF without the direct participation of the nucleus. (24 refs)

78-2776 **Identification of a Polypeptide Encoded by the Avian Sarcoma Virus *src* Gene.** (Eng) Purchio, A. F. (Dept. Microbiology and Immunology, Univ. California Sch. Medicine, Los Angeles, CA, 90024); Erikson, E.; Brugge, J. S.; Erikson, R. L. *Proc Natl Acad Sci USA* 75(3): 1567-1571; 1978.

The use of two procedures to detect a polypeptide encoded by the avian sarcoma virus (ASV) *src* gene is reported. First, antiserum from rabbits bearing ASV-induced fibrosarcomas was used to immunoprecipitate a transformation-specific antigen from ASV-transformed chick embryo fibroblasts. This antigen had an apparent mol wt of 60,000 daltons. Second, the 3′ one-third of the ASV genome, selected by oligo(deoxythymidine)cellulose chromatography and sucrose gradient sedimentation, was translated in a messenger RNA-dependent reticulocyte cell-free lysate. This RNA species programmed the synthesis of a polypeptide that comigrated with the transformation-specific antigen of mol wt 60,000 daltons immunoprecipitated from transformed cells. The methionine-containing tryptic peptides from the 60,000-dalton polypeptides obtained by both methods were identical upon two-dimensional fractionation. (32 refs)

78-2777 **Reversion to the Normal Phenotype by Protein Synthesis Inhibitors Acting on Rat Kidney Cells Transformed by a Temperature-Sensitive Rous Sarcoma Virus Mutant (Meeting Abstract).** (Eng) Carroll, R. (Univ. California at San Diego, La Jolla, CA, 92093); Ash, J. F.; Singer, S. J.; Vogt, P. K. *Fed Proc* 37(6): 1433; 1978. (1 ref)

78-2778 **Characteristics of Cellular RNA Related to the Transforming Gene of Avian Sarcoma Viruses.** (Eng) Spector, D. H. (Dept. Microbiology, Univ. California, San Francisco, CA, 94143); Baker, B.; Varmus, H. E.; Bishop, M. J. *Cell* 13(2): 381-386; 1978.

Nucleotide sequences (*sarc*) related to the transforming gene of avian sarcoma viruses are present in the DNA and transcribed into RNA in uninfected avian cells. Cytoplasmic RNA containing the *sarc* sequences has a sedimentation coefficient of 30S, is linked to polyadenylic acid, and is present in polyribosomes in a form that can be released by EDTA treatment. Thus, the *sarc* sequences (complexity = 5 x 10^5 daltons) are part of a larger transcriptional unit (approx 1.8 x 10^6 daltons), and the *sarc* RNA appears to serve an as yet unknown messenger function. In addition, the *sarc* sequences in chicken cells are not linked to RNA transcribed from the provirus of the endogenous virus RAV-O, since RAV-O cytoplasmic RNA had sedimentation coefficients of 32S and 21S. Comparison of *sarc*-containing RNA in quail embryo fibroblasts and in quail cells derived from a methylcholanthrene-induced fibrosarcoma revealed no differences in the size, polyadenylation, or concentration of the RNA in nuclei, cytoplasm, and polyribosomes. Therefore, phenotypic differences between these cells are unlikely to be a consequence of altered expression of the *sarc* sequences. (17 refs)

78-2779 **Purification and Characterization of Particles Containing RNA-Dependent DNA Polymerase, in the Allantoic Fluid of Uninfected Leukosis Virus-Free Chicken Eggs.** (Eng) Bauer, G. (Max-Planck-Institut fur Biochemie, 8033 Martensried, 6300 Giessen, W. Germany); Friis, R. R.; Jilek, G.; Hofschneider, P. H. *Biochim Biophys Acta* 518(1): 125-137; 1978.

Particles containing particle-associated RNA-dependent DNA polymerase were isolated from the allantoic fluid of embryonated chicken eggs and purified and examined. The particles were obtained from commercially available leukosis virus-free eggs. They did not have the protein composition or sedimentation constant of known avian RNA tumor viruses and they did not exhibit helper activity, interfering properties, or infectivity. Endogenous DNA synthesis was not detected in the particles. The particle-bound enzyme accepted homopolymeric and heteropolymeric RNA as templates and it could synthesize DNA complementary to natural heteropolymeric RNA. These findings indicate that the RNA-dependent DNA polymerase test for leukosis virus can no longer be taken as specific unless the enzyme tested is purified and characterized. (23 refs)

78-2780 **Glial-Mesenchymal Tropism of In Vivo Avian Sarcoma Virus Neuro-oncogenesis in Rats.** (Eng) Copeland, D. D. (Dept. Pathology, Duke Univ. Medical Center, Durham, NC, 27710); Bigner, D. D. *Acta Neuropathol (Berl)* 41(1): 23-25; 1978.

To determine whether avian sarcoma virus (ASV) inoculation during neurogenesis would induce neuronal tumors, the fetuses of 22 pregnant F-344 rats received 5 or 2.5 x 10^5 focus-forming units of the Bratislava-77 strain of ASV between days 17 and 20 of gestation. Inoculations were made into the right cerebral hemisphere of the fetus. Seventeen females delivered 112 live pups, but only 61 could be recovered for autopsy because of hemorrhagic-cyst disease. There were a total of 183 tumors, and most of these were poorly differentiated gliomas (58) or polymorphic astrocytomas (56). No tumor composed of neurons or neuronal precursors was identified. Thus, glial-mesenchymal tropism of in vivo ASV neurooncogenesis is independent of the stage of neurocytodifferentiation at inoculation. (20 refs)

78-2781 **Cell Surface Changes Occurring as Part of the Process of Transformation (Meeting Abstract).** (Eng) Hawkes, S. (Univ. California, Berkeley, CA, 94720); Parry, G. *Fed Proc* 37(6): 1562; 1978. (no refs)

78-2782 **In Vitro Transformation with Avian Myelocytomatosis Virus Strain CMII: Characterization of the Virus and Its Target Cells.** (Eng) Graf, T. (Biologisch-Medizinische Abteilung, Max-Planck-Institut fur Virusforschung, D-7400 Tubingen, W. Germany); Royer-Pokora, B.; Meyer-Glauner, W.; Claviez, M.; Gotz, E.; Beug, H. *Virology* 83(1): 96-109; 1977.

The ability of avian myelocytomatosis virus strain CMII to transform cells from normal SPAFAS chickens was determined. When cells from the bone marrow, yolk sac, and spleen of these chickens were infected with liver extracts and plasma from CMII-infected chickens, transformation foci were noted in 4-6 days. CMII-transformed bone marrow cells could be propagated for up to 15 passages. No differences in the properties of transformed hematopoietic cells from the various organs were noted. The cells closely resembled hematopoietic cells transformed by strain MC29 myelocytomatosis virus, but they differed from avian myeloblastosis virus-transformed cells. The cells were phagocytic, became adherent under certain culture conditions, and required colony-stimulating factor for colony formation in semisolid medium; these properties are characteristic of cells of the granulocyte/macrophage line of differentiation. In contrast to avian erythroblastosis virus, CMII effectively transformed macrophage cultures, suggesting that the target cell belongs to the corresponding differentiation lineage. However, cell-separation experiments showed that the target cells were not identical to normal granulocyte/macrophage colony-forming cells. CMII also induced a morphological transformation of chicken embryo fibroblasts. CMII was found to consist of a mixture of a transforming component and an associated nontransforming virus of subgroup B or D. The transforming component is defective for replication and could be complemented by subgroup B, C, or D helper viruses. (25 refs)

78-2783 **Sites of Integration of Infectious DNA of Avian Reticuloendotheliosis Viruses in Different Avian Cellular DNAs.** (Eng) Battula, N. (NCI, Bethesda, MD, 20014); Temin, H. M. *Cell* 13(2): 387-398; 1978.

The integration pattern of the infectious DNA of spleen necrosis virus (SNV) and chick syncytial virus (CSV), two avian reticuloendotheliosis viruses whose DNA is not inactivated by digestion with the restriction endonuclease Eco RI, was determined. High-mol-wt DNA from infected chicken, turkey, and pheasant cells was digested with Eco RI, electrophoresed through agarose gels, and assayed for infectivity. The integration of SNV and CSV infectious DNA was similar in the three species of avian cells infected at high or low multiplicities of infection. There were multiple sites of integration in acutely infected cells with concomitant cell death. There was a single site of integration in chronically infected cells with no cell death. Compared with chronically infected cells, acutely infected cells contained more integrated infectious viral DNA molecules per cell. These results are consistent with hypotheses that cell death in the acute phase of infection is a result of the integration of infectious viral DNA at multiple sites and that cells survive only when infectious viral DNA is integrated exclusively at a single site. (32 refs)

78-2784 **Effect of Sensitised Leucocytes on Plaque Formation by Marek's Disease Virus.** (Eng) Ross, L. J. (Houghton Poultry Res. Station, Houghton, Huntingdon, Cambs., PE17 2DA, England). *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 179-182; 1978.

Evidence was obtained for the presence in White Leghorn chickens vaccinated against Marek's disease virus (MDV) of circulating T lymphocytes sensitized to virus-specific antigens. The sensitized lymphocytes (SL) inhibited the formation of plaques by syngeneic lymphoid and kidney cells previously infected with MDV. The plaque inhibition occurred as a result of direct interaction between effector cells and cell-surface virus-specific antigens on the target cells, since the SL were removed by absorption to infected but not uninfected monolayers. The capacity of the SL to inhibit plaques was reduced significantly by anti-T serum but not by anti-B or anti-chick immunoglobulin sera. Absolute compatibility between effector and tar was not essential for plaque inhibition, as evidenced by the ability of chick SL to inhibit the formation of infective centers by MDV-infected duck embryo fibroblasts. 78-2785 **Murine and Human Melanomas Containing a High Molecular Weight RNA Associated with an RNA-instructed DNA Polymerase.** (Eng) Hehlmann, R. (Medizinische Poliklinik, Univ. Munich, Pettenkoferstrasse 8a, 8 Munich 2, W. Germany); Balda, B. R.; Spiegelman, S. *Int J Dermatol* 17(2): 114-122; 1978.

The presence of a 70S RNA associated with a reverse transcriptase was detected in murine, hamster, and human melanomas. B16 melanoma isolated from C57BL mice was found to contain 70S RNA-associated reverse transcriptase that back-hybridized to complementary DNA. Mouse melanoma DNA was then hybridized to human and hamster melanoma viral-enriched cytoplasmic RNA. Up to 5.7% of the mouse melanoma DNA hybridized to human melanoma RNA and >7% hybridized to hamster melanoma RNA. These results suggest the presence of melanoma-specific RNA sequences in human and hamster melanomas. The simultaneous detection technique was then applied to 14 human malignant melanomas. Thirteen tumors showed evidence of particles containing a reverse transcriptase and a high-mol-wt RNA. Two specimens from normal skin gave negative responses, but skin near a melanoma gave a positive response. Density determination of the high-mol-wt RNA and reverse transcriptase in human melanoma particles indicated that most of the particles banded at 1.16 g/cm^3, characteristic of RNA tumor viruses. Back-hybridization experiments indicated that labeled tumor DNA combined with the melanoma RNA. Thus, particles possessing characteristics of RNA tumor viruses are found in mouse melanoma B16 and in human melanomas. (28 refs)

78-2786 **Analysis of a 5′ Leader Sequence on Murine Leukemia Virus 21S RNA: Heteroduplex Mapping with Long Reverse Transcriptase Products. Heteroduplex Mapping with Long Reverse Transcriptase Products.** (Eng) Rothenberg, E. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Donoghue, D. J.; Baltimore, D. *Cell* 13(3): 435-451; 1978.

The 5′ terminal sequences of the glycoprotein messenger RNA (mRNA) of murine leukemia virus were investigated to see if the mRNA contained viral sequences from both the 5′ and 3′ ends of the genome. A 5′ probe was made by purifying a discrete 50-nucleotide-long reverse transcript attached to its transfer RNA primer. This probe hybridized to RNA of the size of glycoprotein mRNA--21S, polyadenosine-containing RNA; this indicated that the mRNA could have a 5′ leader sequence. The 5′-specific sequences were studied by electron microscopic examination of hybrids between 21S RNA and the two longest discrete complementary DNA species synthesized in the endogenous reverse transcriptase reaction. One 8.8-kilobase-long species was only made in the absence of actinomycin D; however, it did not contain any self-complementary sequences and it therefore appeared to be a complete transcript of the viral genome. An 8.2-kilobase species was synthesized regardless of the presence of actinomycin D; it terminates 500-600 nucleotides internal to the 5′ end of the template RNA. The structures observed in heteroduplexes of 21S RNA and these DNA's indicated the presence of a leader sequence approx 500 nucleotides long at the 5′ end of the 21S RNA. Sequences comprising this leader segment mapped at the 5′ end of the genome RNA; the remainder of the 21S RNA consisted of sequences from the 3′ portion of the genome. Analysis of heteroduplexes with 8.2-kilobase DNA suggested that actinomycin D could block the reverse transcription of most of the sequence in the genome RNA that appeared as a leader in the 21S RNA. (40 refs)

78-2787 **T1 Oligonucleotide Maps of N-, B-, and B — > NB-tropic Murine Leukemia Viruses Derived from BALB/c.** (Eng) Faller, D. V. (Dept. Biology, Center Cancer Res., Massachusetts Inst. Technology, Cambridge, MA 02139); Hopkins, N. *J Virol* 26(1): 143-152; 1978.

The large RNase T1-resistant oligonucleotides of N-, B-, and NB-tropic murine leukemia viruses derived from BALB/c mice were mapped relative to the 3′ end of the viral RNA. The maps indicated that (1) the large T1 oligonucleotides shared by the N-, B-, and NB-tropic viruses probably occupy the same relative positions on their genomes, (2) the 14 T1 oligonucleotides that differ between the N- and B-tropic viruses are derived from regions scattered along the genomes, and (3) an oligonucleotide that is present in five NB-tropic viruses but not in their B-tropic virus progenitors lies toward the 5′ end of the NB-tropic virus oligonucleotide map. Thus, the determinants of N-tropism reside in the 5′ end of the oligonucleotide map of the N-tropic virus isolate. Conversion from N- to B-tropism might require an alteration in the viral genome at a position corresponding to this portion of the map. (28 refs)

78-2788 **Production and Analysis of a Viral Complex Derived from a Radiation-induced Leukemia Virus of the C57BL Mouse.** (Fre) Mamoun, R. (Unite de Recherches de Radiobiologie Experimentale et de Cancerologie, INSERM Unite 117, 229 cours de l'Argonne, 33076 Bordeaux, France); Guillemain, B.; Astier, T.; Portail, J. P.; Legrand, E.; Duplan, J. F. *Int J Cancer* 22(1): 98-105; 1978.

A radiation leukemia virus (RadLV-Rs) isolated from a C57BL mouse with radiation-induced leukemia was shown to induce lymphoreticular cell neoplasms of the spleen and lymph nodes rather than thymomas. Several cell lines established in culture from the spleen and lymph node tumors were originally composed of round virus-producing cells, but their ability to produce virus disappeared progressively upon serial passage. Simultaneously, the cells grew as a monolayer of polygonal epitheliallike cells. In several clones derived from one of the tumor cell lines, the presence of round cells correlated positively with viral release. Besides these morphological differences, the karyotype of the virus-producing clones was strongly modified. Cells of clone 13-3C (producing a virus called 13C) contained 43 chromosomes, a large number of which were metacentric. In contrast, clone 13-2D, which had the same origin as 13-3C but did not produce virus, had 70 acrocentric chromosomes. Virus 13C had the same pathogenic effects as the original RaLV-Rs; on the basis of its biochemical and morphological properties, it was classified as a C-type retrovirus, and it also induced Gross-type cell-surface antigens. Unlike most murine leukemia viruses (MuLV), this virus did not show any helper activity for the murine sarcoma virus (MSV) integrated in S+L-mouse cells. However, syncytia formation was readily observed after cocultivation of 13-3C and XC cells. The 13C virus was shown to be a complex composed of an ecotropic MuLV that preferentially infects B-type mouse cells (MuLV-B) and a xenotropic virus (MuLV-X). The MuLV-B had no helper activity for integrated MSV and did not induce XC syncytia formation. The MuLV-X was a potent helper for MSV in S+L-mink cells, but it did not induce XC syncytia formation. (37 refs)

78-2789 **Loss of Immunosuppressive Potential in a Highly Leukemogenic Clone of Murine RNA Tumor Virus, 334C (Meeting Abstract).** (Eng) Robinson, M. K. (Roswell Park Memorial Inst., Buffalo, NY, 14263); Evans, M. J.; Manly, K. F. *Fed Proc* 37(6): 1570; 1978. (no refs)

78-2790 **Relationships of gp70 of MuLV Envelopes to gp70 Components of Mouse Lymphocyte Plasma Membranes.** (Eng) Tung, J. S. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); O'Donnell, P. V.; Fleissner, E.; Boyse, E. A. *J Exp Med* 147(4): 1280-1284; 1978.

To investigate the relationship of viral gp70's to plasma-membrane gp70's, peptide maps of tryptic digests of gp70 bands obtained by sodium dodecyl sulfate-polyacrylamide gel electrophoresis of immunoprecipitated cell lysates were compared with maps of plasma-membrane gp70's from cultured cells infected by ecotropic or xenotropic murine leukemia viruses. Maps of gp70's from cells infected with ecotropic and xenotropic viruses were distinguishable from one another, and in general they resembled the gp70 maps prepared directly from ecotropic and xenotropic virions, respectively. Maps of gp70's immunoprecipitated from thymocytes of five mouse strains and from two A-strain T-cell leukemias also showed two distinguishable and generally corresponding patterns, indicating that viral gp70's and plasma-membrane gp70's inherited independently of virus production are closely related or identical molecules. The gp70 maps of thymocytes from B6, B6-G(IX)+, 129, and A mice resembled the gp70 map of cultured cells infected with xenotropic virus, whereas thymocytes from AKR mice and the two A-strain leukemias yielded gp70 maps conforming more to the pattern of cultured cells infected with ecotropic virus. The data indicate that the G(IX)-gp70 and O-gp70 subspecies of gp70 expressed in the cell populations studied are coded by xenotropic viral genomes and that X-gp70 is coded by ecotropic viral genomes. (14 refs)

78-2791 **Gene Order of the Mouse Mammary Tumor Virus Glycoproteins.** (Eng) Schochetman, G. (Viral Oncology Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Oroszlan, S.; Arthur, L.; Fine, D. *Virology* 83(1): 72-83; 1977.

Immunochemical and tryptic peptide mapping techniques were used to determine the derivation and gene order of the mouse mammary tumor virus (MMTV) envelope glycoproteins gp52 and gp36. According to these techniques, gp52, gp36, and p27 are distinct components. The following evidence indicated that gp52 and gp36 are derived from a common glycosylated precursor polypeptide of 75,000 daltons (gpPr75) representing the MMTV *env* gene: (1) monospecific antisera directed against both gp52 and gp36 each precipitated gPr75; (2) during pulse-chase experiments, a decrease in the amount of gPr75 was always accompanied by an increase in the amount of gp52 and gp36; (3) polypeptide gPr75 incorporated ^{3}H-glucosamine; and (4) kinetic analysis of MMTV protein synthesis demonstrated that gp52 and gp36 were synthesized sequentially, not simultaneously. The gene order of gp52 and gp36 was deduced from three different types of experiments: measurement of the differential inhibition by NaCl hypertonic shock on initiation of gp52 and gp36 synthesis; measurement of the kinetics of appearance of various MMTV proteins following the synchronized reinitiation of polypeptide synthesis resulting from NaCl hypertonic shock; and analysis of the polypeptides released from polyribosomes after a series of variable-length short pulses with ^{3}H-amino acids. The results indicate that the gene order for gPr75 within the MMTV genome is H_2N-gp52-gp36-COOH and 5′-gp52-gp36-3′. (18 refs)

78-2792 **In Vitro Transcription of Mouse Mammary Tumor Virus RNA into DNA.** (Eng) Taylor, J. M. (Inst. Cancer Res., Fox Chase Cancer Center, Philadelphia, PA, 19111); Illmensee, R.; Young, H. A. *J Virol* 25(2): 693-694; 1978.

Polyacrylamide gel electrophoresis of [^{32}P]-deoxy-ATP-labeled nucleic acids extracted from detergent-labeled virions showed that the RNA-directed DNA synthesis of B-type mouse mammary tumor virus is similar to that of the avian leukosis-sarcoma and murine leukemia viruses. The synthesis can be initiated on an RNA primer molecule approx the size of a transfer RNA, and a unique linkage (rA-dC) exists between this primer and the DNA product. (6 refs)

78-2802 **Effect of Pseudotype on Abelson Virus and Kirsten Sarcoma Virus-induced Leukemia.**

(Eng) Scher, C. D. (Sidney Farber Cancer Inst., Boston, MA, 02115). *J Exp Med* 147(4): 1044-1053; 1978.

To study the effect of virus pseudotype on leukemogenesis, a newborn Swiss or DBA/2 mice were inoculated with Abelson murine leukemia virus (A-MuLV) or Kirsten sarcoma virus (KiSV) rescued from nonproducer cells with several N- or NB-tropic helper viruses. The Friend, Moloney, and Rauscher (FMR) group of MuLV pseudotypes of KiSV induced an erythroid leukemia efficiently, whereas an endogenous helper pseudotype (N35-MuLV) did not. The FMR pseudotypes of A-MuLV induced Abelson lymphoid leukemia, but N35-MuLV and a Kirsten leukemia virus (Ki-MuLV) pseudotype did not. Pseudotypes of A-MuLV were also used to infect bone marrow cells of Fv-1nn mice in vitro. The FMR pseudotypes transformed bone marrow cells at a 40- to 100-fold higher frequency than did the N35-MuLV and Ki-MuLV pseudotypes. Mixing experiments demonstrated that the addition of an effective helper, such as M-MuLV, did not enhance lymphoid transformation by ineffective A-MuLV(N35-MuLV). Isolation of an A-MuLV-transformed clone of nonproducer lymphoid cell indicated that the A-MuLV component of A-MuLV(M-MuLV) was responsible for hematopoietic cell transformation. The data indicate that the pseudotype of A-MuLV determines its ability to transform hematopoietic cells. (24 refs)

78-2803 **The Effect of Helper Virus on Abelson Virus-induced Transformation of Lymphoid Cells.** (Eng) Rosenberg, N. (Dept. Pathology, Tufts Univ. Sch. Medicine, Boston, MA, 02111); Baltimore, D. *J Exp Med* 147(4): 1126-1141; 1978.

The oncogenic activity and transforming ability of Abelson murine leukemia virus (A-MuLV) prepared with several different helper viruses were tested to determine the role of helper virus in A-MuLV-induced transformation. Transforming ability was determined in vitro using bone marrow cells from 4- to 6-wk-old mice, and oncogenicity was determined by injection of virus into NIH/Swiss, BALB/cAN, CD-1/Swiss, and C57BR/cdJ mice. All of the A-MuLV stocks transformed NIH/3T3 or BALB/3T3 fibroblasts efficiently, indicating that all of the murine retroviruses tested were equivalently effective helpers. However, only A-MuLV stocks prepared with highly oncogenic helper viruses were able to transform hematopoietic cells efficiently in vitro and in vivo. A-MuLV prepared with weakly oncogenic helpers was highly inefficient as a transforming agent in vivo and in vitro. Inefficient helpers were also unable to establish a stable infection in lymphoid nonproducer cells. The results suggest that the helper virus may play a more active role in lymphoid cell transformation than in fibroblast transformation. (30 refs)

78-2804 **Existence of a Reverse Transcriptase-P30 Complex in AKR Mice with a High Incidence of Spontaneous Lymphocytic Leukemia (Meeting Abstract).** (Eng) Bandyopadhyay, A. K. (NIH, NCI, Baltimore Cancer Res. Center, Baltimore, MD, 21211); Mardiney, M. R.; Levy, C. C. *Proc Am Assoc Cancer Res* 19: 220; 1978. (no refs)

78-2805 **Oncogenicity of AKR Endogenous Leukemia Viruses.** (Eng) Nowinski, R. C. (Fred Hutchinson Cancer Res. Center, Seattle, WA, 98104); Hays, E. F. *J Virol* 27(1): 13-18; 1978.

On the basis of infectious properties in tissue culture, four biologically distinct types of endogenous murine leukemia virus (MuLV) have been isolated from AKR mice. They include: (1) ecotropic XC^+ MuLV, which occurs in high titer in normal tissues and serum of AKR mice throughout their life-span; (2) ecotropic XC^- MuLV, produced in high titer by leukemia cells; (3) xenotropic MuLV, readily demonstrated only in aged mice; and (4) polytropic MuLV, which arises in the thymuses of aged mice as a result of genetic recombination between ecotropic and xenotropic MuLV. All four types can be isolated from the thymuses of leukemic mice. However, leukemia cell lines in culture tend to produce a predominance of type 2 virus, suggesting that the other types may be produced by nonleukemic cells in the thymus. Isolates of types 2 and 4 virus had high oncogenic activity in AKR mice: 100% developed leukemias within 90 days of inoculation. In contrast, types 1 and 3 did not demonstrate oncogenic activity. The results show that there are fundamental differences between XC^- and XC^+ ecotropic MuLV and that ecotropic XC^- and polytropic MuLV are involved in the spontaneous leukemogenesis of AKR mice. It is hypothesized that the accelerated induction of leukemia in these mice is the result of in vivo interaction between viruses and that XC^- MuLV, because of its inefficient replication properties, preferentially recombines with xenotropic MuLV to yield an efficiently replicating polytropic MuLV that is highly oncogenic. 78-2806 **High-Molecular-Weight RNAs of AKR, NZB, and Wild Mouse Viruses and Avian Reticuloendotheliosis Virus All Have Similar Dimer Structures.** (Eng) Bender, W. (Div. Biology, Dept. Chemistry, California Inst. Technology, Pasadena, CA, 91125); Chien, Y. H.; Chattopadhyay, S.; Vogt, P. K.; Gardner, M. B.; Davidson, N. *J Virol* 25(3): 888-896; 1978.

Tumor viral 50S-70S RNA's from the AKR-L1 strain of ecotropic murine leukemia virus, NZB murine xenotropic virus, an ecotropic and an amphotropic virus isolated from a wild mouse, and avian reticuloendotheliosis virus (REV) were studied to determine the degree of homology of their dimer structures. The RNA's of AKR, NZB, the ecotropic wild mouse virus, and REV each showed a single band on agarose gel corresponding to estimated molecular lengths of 9.6, 9.5, 9.3, and 9.2 kilobases, respectively. Amphotropic wild mouse virus RNA was not present in sufficient quantities for electrophoresis. All five 50S-70S RNA's had similar 5′-5′ dimer structures. These observations support the hypothesis that the dimer linkage is a structural feature common to all C-type mammalian viruses. All of the mammalian viral RNA's, but not those of REV, demonstrated symmetrically placed loops in each subunit of the dimer. Thermal stability measurements with REV RNA indicated that at 55 C, 90% of the RNA still migrated as 50S-70S, but that at 65 C, the RNA was 90% dissociated to 35S. With NZB, heating to 80 C did not affect migration, but heating to 100 C disrupted all migration. The RNA's of AKR and the wild mouse viruses were not available for thermal stability measurements. (30 refs)

78-2807 **Properties of Mouse Leukemia Viruses. XV. Electron Microscopic Studies on the Organization of Friend Leukemia Virus and Other Mammalian C-Type Viruses.** (Eng) Frank, H. (Max-Planck-Institute fur Virusforschung, Spemannstrasse 35, D-7400 Tubingen 1, W. Germany); Schwarz, H.; Graf, T.; Schafer, W. *Z Naturforsch C* 33(1/2): 124-138; 1978.

The structural organization of various mammalian C-type viruses was investigated. Investigations of Friend leukemia virus (FLV) revealed that transition from the native to the collapsed form occurs mainly during preparation for electron microscopy. A short pretreatment of the virus with the detergent Nonidet P40 prior to negative staining with uranyl acetate preserved the native structure in a high percentage of virus particles from standard preparations. This technique was then used to study the internal organization of the virus. A thin inner coat was detected in close apposition to the viral membrane between the viral envelope and core. Removal of the unit membrane by more intensive detergent treatment revealed the existence of material extending between the viral surface knobs and the viral interior. The icosahedral core shell had an opening at one side and this corresponded to an opening in the helically arranged ribonucleoprotein strand representing the innermost structure. A comparative study of the structures of representative mammalian C-type viruses revealed that they were similar to that of Friend virus; differences in stability, however, were observed. It is thus suggested that C-type viruses contain knobs known to represent the virus glycoprotein and that these knobs are anchored in the viral membrane. The inner coat is either inside this viral membrane or is part of it. Between the envelope and the core lies the material that apparently links the knobs to the core. The core shell contains an opening representing the site of the shell synthesized last during budding. It is suggested that the ribonucleoprotein represents a wound-up thread forming a helical structure. Its opening is closely apposed to the opening in the core shell. (32 refs)

78-2808 **Identification of a Gene (Fv-3) Which Regulates Susceptibility to Immunosuppression by Friend Virus Complex (FV) (Meeting Abstract).** (Eng) Kumar, V. (Dept. Pathology, Boston Univ. Sch. Medicine, Boston, MA, 02118); Bennett, M. *Fed Proc* 37(6): 1570; 1978. (no refs)

78-2809 **Variations in Viral Gene Expression in Friend Virus-transformed Cell Lines Congenic with Respect to the *H-2* Locus.** (Eng) Freedman, H. A. (Dept. Pathology, State Univ. New York, Downstate Medical Center, Brooklyn, NY, 11203); Lilly, F.; Strand, M.; August, J. T. *Cell* 13(1): 33-40; 1978.

The effect of *H-2* genotype on the genetic expression of Friend oncovirus was studied using Friend virus (FV)-transformed cells differing genetically only at the *H-2* locus. Seven lines and three sublines were derived from solid tumors obtained by sc transplantation of fragments from the enlarged spleens of FV-infected mice to syngeneic recipients. Upon serial passage, the *H-2b*, *H-2g*, and *H-2kb* cell lines were stable for the production of infectious FV, whereas the *H-2a* and *H-2k* cell lines stopped releasing infectious virus after a relatively short time. Synthesis of viral proteins by these cell lines was independent of the synthesis of infectious virus in that some viral proteins continued to be synthesized by *H-2a* and *H-2k* in the absence of infectious virus. The temporal sequence of change suggests that the loss of protein expression may have occurred sequentially: reverse transcriptase was reduced first, followed by the structural proteins p30 and p15, and then the envelope glycoprotein gp69/71. While p30 and p15 were coordinately expressed, p30 and gp69/71 were not, indicating that these proteins are regulated by independent genetic loci. Loss of viral genes did not occur, because cell lines that had previously ceased to synthesize viral proteins could be chemically induced to produce infectious FV. These data suggest that for these *H-2*-congenic cell lines, there is an association of the *H-2Db* allele and the long-term production and release in vitro of both infectious virus and viral proteins. (27 refs)

78-2810 **Studies on the Nature of the Cell Surface Antigen Reacting with Cytolytic T Lymphocytes in Murine Oncornavirus-induced Tumors.** (Eng) Gomard, E. (Laboratoire d'Immunologie et de Virologie des Tumeurs, INSERM U 152, Hopital Cochin, 27 Rue du Faubourg Saint Jacques, F-75674 Paris Cedex 14, France); Levy, J. P.; Plata, F.; Henin, Y.; Duprez, V.; Bismuth, A.; Reme, T. *Eur J Immunol* 8(4): 228-236; 1978.

In the murine sarcoma virus (MSV) system, the activity of the tumor cell surface antigen that reacts with cytolytic T lymphocytes (CTL) is under histocompatibility (H-2) antigen restriction. This was shown in systematic experiments, including chromium-release tests lasting 3-4 and 16-20 hr. With the 16- to 20-hr tests, however, quantitative methods were necessary to demonstrate H-2 restriction. These results support the hypothesis that H-2 molecules may be determinants in the structure and/or function of the CTL reactive antigen. Under syngeneic conditions (ie, using H-2-identical immune lymphocytes, stimulators, and target cells), the pattern of specificities recognized by anti-MSV or anti-Friend leukemia virus T cells on 20 different lymphomas suggested that the main reactive antigen is an 'FMR-like' (Friend, Moloney, Rauscher) substance. Identical conclusions were drawn from competition experiments. The CTL-mediated reaction was blocked by preincubation of target cells with goat antisera against the viral glycoprotein gp70, which suggested an association between the FMR antigen and gp70. However, this might have been due to nonspecific reactions, as two other gp70 antisera and antisera against the viral components gp45, pr60, p30, p15, p12, and p10 lacked blocking activity. The CTL/tumor cell interaction was not inhibited by virion-associated antigens added to the medium. Lysostrip and cocapping experiments failed to reveal an association between H-2 and gp70. The nature of the viral protein bearing the 'FMR-like' substance, therefore, remains to be established. (48 refs)

78-2811 **Virulence of Clones of Friend Leukemia Virus Complex Expressing Different Immunosuppressive Properties (Meeting Abstract).** (Eng) Eckner, R. J. (Boston Univ. Sch. Medicine, Boston, MA, 02118); Scherzer, L. J. *Fed Proc* 37(6): 1570; 1978. (no refs)

78-2812 **Rfv-1 and Rfv-2, Two H-2-associated Genes that Influence Recovery from Friend Leukemia Virus-induced Splenomegaly.** (Eng) Chesebro, B. (Dept. Health, Education and Welfare, Rocky Mountain Lab., Natl. Inst. Allergy and Infectious Diseases, Hamilton, MT, 59840); Wehrly, K. *J Immunol* 120(4): 1081-1085; 1978.

The influence of genes of the mouse major histocompatibility complex (*H*-2) on recovery from Friend murine leukemia virus (FV)-induced leukemia was studied using the congeneic F_1 hybrid strains differing only at genes of the *H*-2 complex and *Tla* region. Two genes influenced recovery from FV-induced leukemia: *Rfv*-1 and *Rfv*-2. *Rfv*-1 was located to the left of the *Tla* region within the *H*-2 complex, specifically, in the *H-2G* or *H-2D* regions. *Rfv*-2 was located in the *H*-2 *K* or *H-2I* regions or in the *Tla* region. Since the *Rfv*-2 effect was not seen in *H-2D(Rfv-1)b/b* mice, which show a high recovery rate from FV leukemia, this gene may have a weaker influence than *Rfv*-1 on recovery from leukemia. The *H*-2 effect on recovery appeared to function in a gene-dose fashion. This effect may act on the kinetics of induction in virus-specific cytotoxic T cells. (29 refs)

78-2813 **Transformation-dependent Secretion of a Low Molecular Weight Protein by Murine Fibroblasts.** (Eng) Gottesman, M. M. (Lab. Molecular Biology, NCI, NIH, Bethesda, MD, 20014). *Proc Natl Acad Sci USA* 75(6): 2767-2771; 1978.

The major excreted proteins from transformed and untransformed murine cells were characterized by a pulse-chase protocol that radiolabels proteins secreted by cells in culture. A radiolabeled 35,000-mol wt polypeptide was released into the medium in relatively large amounts (0.1%-1% of total protein synthesized) by Kirsten virus-transformed NIH Swiss 3T3 cells but in much smaller amounts (≤ 0.02% of total protein synthesized) by untransformed 3T3 cells. In experiments performed to establish whether secretion of this major excreted polypeptide (MEP) is related to transformation, it was found that BALB/c cell strains transformed spontaneously or by RNA tumor viruses (Kirsten, Moloney sarcoma viruses), a DNA tumor virus (simian virus 40), or by methylcholanthrene all excreted relatively large amounts of MEP. In contrast, the parental cell line secreted barely detectable levels of this polypeptide. MEP appearance seemed to correlate well with anchorage independence in the transformed cells. Indirect immunofluorescence showed that MEP was localized within the cytoplasm of the transformed cells and that it is not a cell-surface protein. The presence of MEP may serve as a biochemical marker of transformation. A biological role for this protein has not been assigned. (21 refs)

78-2814 **High Molecular Weight Viral Reverse Transcriptase in Moloney Sarcoma Virus Transformed Cells.** (Eng) Rokutanda, M. (Dept. Biochemistry, Tokyo Metropolitan Inst. Medical Science, Tokyo 113, Japan); Maeda, Y.; Watanabe, N. *Biochem Biophys Res Commun* 80(4): 729-734; 1978.

Viral reverse transcriptase (RT) was isolated and purified from Moloney sarcoma virus-transformed rat cells by ion-exchange chromatography and density gradient centrifugation. The time course of the mol wt shift of the viral RT from the cytoplasmic form to the virion form was examined by harvesting the virus after 20 min, 2 hr, and 4 hr incubation and determining the mol wt of the enzyme from glycerol gradient centrifugation. The cytoplasmic RT and the RT from the virions harvested at 20 min had a mol wt of 105,000. A small amount of a 70,000-mol wt enzyme was also included in the 20-min sample. At 2 hr incubation, the enzyme consisted mainly of a 70,000-mol wt protein and a small amount of a 105,000-mol wt protein. At 4 hr incubation, the mol wt of the viral RT was 70,000. It is suggested that the viral RT was present in the cytoplasm as the high-mol-wt form and that maturation of the enzyme (to the low-mol-wt form) occurs in the virus particles immediately after budding of the particles from the cell surface. (8 refs)

78-2815 **Large T1 Oligonucleotides of Moloney Leukemia Virus Missing in an *env* Gene Recombinant, HIX, Are Present on an Intracellular 21S Moloney Viral RNA Species.** (Eng) Faller, D. V. (Biology Dept., Massachusetts Inst. Technology, Cambridge, MA); Rommelaere, J.; Hopkins, N. *Proc Natl Acad Sci USA* 75(6): 2964-2968; 1978.

HIX, a dual tropic virus whose ecotropic parent is Moloney leukemia virus, has an envelope glycoprotein different from that of Moloney virus. HIX and Moloney viruses share most of the large T1 oligonucleotides derived from their genomes, but each possesses a set of distinctive oligonucleotides that lie clustered in corresponding regions in the 3′ halves of their oligonucleotide maps. These regions presumably contain envelope glycoprotein coding sequences. The C-type viral envelope glycoprotein is believed to be translated from a 21S RNA. Thus, at least part of the region of the Moloney virus genome that is altered relative to HIX was expected to be present on such a species. To test this prediction, an intracellular 21S Moloney viral RNA species was purified and its large T1 oligonucleotides were analyzed by two-dimensional polyacrylamide gel electrophoresis. This RNA contains one T1 oligonucleotide that is probably derived from the 5′ end of the Moloney virus genome, the Moloney virus T1 oligonucleotides that are missing in HIX, and those that lie to their 3′ side on the Moloney virus T1 oligonucleotide map. (25 refs)

78-2816 **Oncornavirus-induced Autoaggression and Lymphomagenesis: The Obverse of Altered-Self?** (Eng) Proffitt, M. P. (Dept. Immunology, Cleveland Clinic Foundation, Cleveland, OH, 44106); Vessey, A. R.; Del Villano, B. C. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 84-87; 1978.

Normal C3H/He mouse embyro cells at low passage levels ($P < 25$) were consistently killed by thymocytes from adult C3H/HeJ mice infected with Moloney murine leukemia virus (M-MuLV) since birth. However, the target cells lost their susceptibility to killing at high passage levels ($P > 30$). This resistance to the M-MuLV-carrier thymocytes correlated with the spontaneous expression of the viral envelope glycoprotein gp70 and of infectious ecotropic MuLV by the target cells. Possible factors involved in these phenomena are discussed. (12 refs)

78-2817 **Selective Amplification of Murine Sarcoma Virus Proviral DNA in Productively Infected Mammalian Cells.** (Eng) Frankel, A. E. (NCI, Bethesda, MD, 20014); Fischinger, P. J. *In: Advances in Comparative Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 171-173; 1978.

The mechanisms by which helper viruses augment the morphologic transformation of various mammalian cell lines by Moloney murine sarcoma virus (M-MSV) were studied. Complementary DNA (cDNA)-cellular DNA hybridizations were performed using MSV-murine leukemia virus cDNA for cat and dog systems and MSV-specific cDNA for human and mouse systems. Human sarcoma positive, leukemia negative cells (S+L- cells) and cat, dog, or mouse cells transformed by M-MSV contained 1-2 copies of M-MSV proviral DNA. In each system, the number of MSV proviral DNA copies increased from three- to tenfold after superinfection with helper viruses, including ecotropic mouse leukemia virus, feline leukemia and feline endogenous xenotropic viruses, and simian sarcoma-associated virus. In cells that did not contain leukemia-related sequences, helper virus infection resulted in the appearance of only a few copies of the helper leukemia proviral DNA. The amplification of M-MSV DNA by helper virus superinfection was accompanied by increases in MSV RNA and viral proteins and in the degree of morphological transformation. (1 ref)

78-2818 **Amino-Terminal Amino Acid Sequence and Carboxyl-Terminal Analysis of Rauscher Murine Leukemia Virus Glycoproteins.** (Eng) Henderson, L. E. (Viral Oncology Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Copeland, T. D.; Smythers, G. W.; Marquardt, H.; Oroszlan, S. *Virology* 85(1): 319-322; 1978.

The results of amino acid analyses, NH_2-terminal sequence determinations, and carboxypeptidase digestions of Rauscher murine leukemia virus glycoproteins gp80 and gp45 are presented. The two gp had the following identical NH_2-terminal amino acid sequences: Ala-Ala-Pro-Gly-Ser-Ser-Pro His-Gln-Val-Tyr-X-Ile-Thr-X-Glu-Val- (X, unidentified) The COOH-terminal amino acid is tyrosine for gp7 and leucine for gp45. Computer-analyzed amino aci compositional data indicated that the protein component in gp45 is smaller (approx 36,000) than that n gp70. These data provide compelling evidence that gp45, which also contains less carbohydrate, is derived from gp70 through proteolysis that may or may not be accompanied by glycolytic cleavage(s). The alternative that gp45 may be generated from the nonglycosylated or partially glycosylated precursor cannot be excluded completely. The results suggest that the two gp are not encoded separately in he viral genome. (25 refs)

8-2819 **Impaired Processing of Precursor Polypeptides of Temperature-sensitive Mutants of Rauscher Murine Leukemia Virus.** (Eng) van de Ven, W. J. (Dept. Biochemistry, Univ. Nijmegen, Nijmegen, Netherlands); van Zaane, D.; Onnekink, C.; Bloemers, H. P. *J Virol* 25(2): 553-561; 1978.

The synthesis and processing of virus-specific polypeptides n NIH/3T3 cells infected at the permissive temperature (31 C) with temperature-sensitive (*ts*) mutants of Rauscher murine leukemia virus (R-MLV) were studied in pulse-chase experiments at the permissive and nonpermissive (39 C) temperatures. The viral polypeptides were identified by sodium dodecyl sulfate-polyacrylamide gel electrophoresis after immunoprecipitation with polyvalent and monospecific anti-R-MLV sera. In cells infected with *ts* mutants defective in early replication steps (*ts*17 and *ts*20) or *ts* mutants defective in postintegration steps (*ts*25 and *ts*26), the processing of the primary *gag* gene product was impaired at 39 C. In all four mutants, *gag*-pr75 was converted into *gag*-pr65; however, *gag*-pr65 accumulated at 39 C, and the main internal virion polypeptide p30 was not formed. Therefore, he proteolytic cleavage was blocked beyond *gag*-pr65. Concomitantly, the formation of the *env* gene-related polypeptide p12(E) of all four mutants was blocked at the restrictive temperature. In contrast, cells inected with the late mutant *ts*28, which produced nfectious virions at 39 C, showed a normal turnover of the *gag* and *env* precursor polypeptides. (27 refs)

78-2820 **Virion Precipitation Test Based on the Determination of Reverse Transcriptase Activity: Analysis of Oncornavirus Surface Antigens.** (Rus) Zakharova, L. G. (D. I. Ivanovsky Inst. Virology, Moscow, USSR); Al'tshtein, A. D. *Vopr Virusol* (1): 19-24; 1978.

A new method for assessing oncornavirus surface antigens s described. The concentrates of a series of 11 oncornaviruses Rauscher murine leukemia virus, Gross murine leukemia virus, endogenous virus from NIH Swiss mice, exogenous eline leukemia virus, Rous sarcoma virus, murine mammary umor virus, etc.) showing marked reverse transcriptase acivity were incubated with immune goat sera against the test viruses. The precipitate was centrifuged, and the supernatant was tested in the reverse transcriptase reaction. Incubation with immune sera resulted in the precipitation of 80%-100% reverse transcriptase activity (compared with 22%-42% precipitation after incubation with normal sera). Immune sera precipitated only homologous virus. (5 refs)

78-2821 **Studies on Aminoglycolipid Contents and Their Synthesis in Hamster Cell Lines. Polyoma-transformed BHK Cell Lines with Low β- and High α-N-Acetylgalactosaminyltransferase Activities.** (Eng) Yokosawa, N. (Biochemical Lab., Cancer Inst., Hokkaido Univ. Sch. Medicine, Sapporo 060, Japan); Kijimoto-Ochiai, S.; Makita, A. *Biochim Biophys Acta* 528(1): 138-147; 1978.

The aminoglycolipid contents of baby hamster kidney (BHK) cells and polyoma (Py)-transformed BHK cells were investigated and compared with those of NIL-2K hamster cells. The amount of globoside in the BHK cells was larger than that in the BHK-Py cells, but thin-layer chromatography indicated that both lines contained little Forssman hapten. Hemolysis inhibition studies indicated that Forssman hapten was synthesized in BHK and BHK-Py cells, but that the amount was small in comparison with NIL-2K and NIL-Py cells. When glycolipid β- and α-N-acetylgalactosaminyltransferases were assayed with enzyme preparations, BHK-Py cells showed little β-transferase (globoside synthesis) activity and elevated α-transferase (Forssman hapten synthesis) activity compared with the parent BHK cells. This suggested that the low β-transferase activity results in low levels of both the aminoglycolipids. The properties of the α-transferase of both lines were similar. There was no inhibitor of this enzyme in BHK cells and no activator in BHK-Py cells. (26 refs)

78-2822 **Increased Trypsin Sensitivity of Cell Surface Macromolecules after Malignant Transformation.** (Eng) Latner, A. L. (Cancer Res. Unit, Univ. Dept. Clinical Biochemistry, Royal Victoria Infirmary, Newcastle upon Tyne, England); Turner, G. A. *Exp Cell Biol* 46(5): 298-309; 1978.

The effect of standard trypsin treatment (STT: 400 μg/ml for 3 hr) on the electrophoretic mobility (EPM) of baby hamster kidney (BHK21) cells and their polyoma virus-transformed counterparts (Py6 cells) was investigated. In a previous study, these conditions had resulted in the release of material from the Py6 cells, but not the BHK21 cells. STT increased the mean EPM of the transformed cells significantly, from -2.07 to -2.41 μm·sec^{-1}· V^{-1}·cm. This change was not observed when the cells were incubated in the absence of trypsin, and STT of the BHK21 cells did not change their mean EPM. Increasing the incubation time to 6 hr had no significant effect, but decreasing this time to 1 hr gave a mean EPM that was the same as that of untreated cells. Treatment of Py6 cells with 200 μg/ml trypsin still increased their EPM significantly, but to a significantly lower degree than that produced by STT. Active enzyme was required to produce the change. No evidence was obtained for cytolysis, cytotoxicity, or uptake of the enzyme by the treated Py6 cells. Measurement of the EPM of the Py6 cells at different pH levels before and after treatment suggested that the enzyme was removing cationic groupings from the cell surface. The increase in EPM of Py6 cells after STT may be the result of a direct enzyme attack on molecules that contribute to the EPM of the cells. The trypsin-sensitive positive component of the cell-surface charge, present only on the transformed cells, may be important in the expression of the malignant characteristics of the cancer cell. (40 refs)

78-2823 **Endogenous Guinea Pig Retrovirus: Its Expression in Leukemic Guinea Pig Cells.** (Eng) Davis, A. R. (Dept. Microbiology and Immunology, Univ. California Sch. Medicine, Los Angeles, CA, 90024); Nayak, D. P.; Lofgren, J. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 176-178; 1978.

Molecular hybridization of viral complementary DNA to cellular RNA was used to study the expression of guinea pig retrovirus ([5-bromodeoxyuridine (BUdR)-induced GPV]) in L_2C leukemic lymphoblasts. Although the leukemic cells contained fewer copies of viral RNA per cell than the BUdR-induced cells, the results indicated the essentially complete expression of the BUdR-induced GPV genes in the leukemic cells. Both BUdR-induced cells and L_2C lymphoblasts contained 14S, 22S, 35S, and 70S RNA species of total and cytoplasmic virus-specific RNA. In addition, BUdR-induced GPV-specific messenger RNA (mRNA) was present in polyribosomes and leukemic lymphoblasts: 14S, 20S, and 35S mRNA species, the same as those observed in BUdR-induced cells, were identified. (8 refs)

78-2824 **The Frequency of Occurrence of Feline Leukaemia Virus Subgroups in Cats.** (Eng) Jarrett, O. (Dept. Veterinary Pathology, Veterinary Sch., Univ. Glasgow, Glasgow G61 1QH, Scotland); Hardy, W. D.; Golder, M. C.; Hay, D. *Int J Cancer* 21(3): 334-337; 1978.

Feline leukemia viruses (FeLV) were isolated from cats in Glasgow and New York with lymphosarcoma and from apparently healthy carrier cats, and the subgroup composition of each isolate was determined. The majority of isolates consisted of either FeLV-A alone or FeLV-A and B; FeLV-C was rare, and it occurred in mixtures that included FeLV-A. Of healthy cats, 65% had FeLV-A alone and 33% had FeLV-AB, but of leukemic cats, 42% had FeLV-A and 58% had FeLV-AB. This same pattern was noted in both Glasgow and New York. No correlation was noted between a particular virus subgroup and any of the common types of lymphosarcoma or leukemia in cats. FeLV-C was found only in one cat with leukemia and two others with aplastic anemia. The viruses isolated from the two latter were mixtures of subgroups A and C and A, B, and C respectively. Isolates were also studied in cats from 25 British multiple-cat households (MCH). In 15 MCH, FeLV-A alone was isolated; in 10, isolates containing either FeLV-A or FeLV-AB were found. Of the MCH in which FeLV-AB was found, half yielded FeLV-A and half yielded FeLV-AB. Overall, the proportion of FeLV-infected cats in MCH was 42%. In MCH in which only FeLV-A was isolated, 28% were FeLV-positive, but in MCH with FeLV-AB, 53% of the cats were infected. (9 refs)

78-2825 **Dissemination of Bovine Oncornavirus among Cattle from Leukemic Herds.** (Rus) Valikhov, A. F. (All-Union Inst. Experimental Veterinary Medicine, Moscow, USSR); Burba, L. G.; Nakhmanson, V. M.; Zinevich, L. A.; Kozin, A. F.; Golovchenko, A. P.; Guliukin, M. I.; Ezovitov, N. B.; Borodin, A. G. *Veterinariia* (3): 40-43; 1978.

Cattle from herds with a high incidence of leukemia (up to 57%) were investigated for antibodies to oncornavirus. Antibodies were found in 281/769 animals in one herd and in 290/2,412 in another. Most of the positive animals were 3-5 yr old. However, only 20% of the oncornavirus-infected animals had leukemia; most of these animals were 3-4 yr old. The hematological parameters of most of the virus-infected animals were normal. (no refs)

78-2826 **Infection of Human Cell Cultures with Bovine Visna Virus.** (Eng) Georgiades, J. A. (Rega Inst. Medical Res., Univ. Leuven, Minderbroedersstraat 10, B-3000 Leuven, Belgium); Billiau, A.; Vanderschueren, B. *J Gen Virol* 38(2): 375-381; 1978.

The possibility that bovine visna virus (BVV) could infect and transform human cells was investigated using fibroblastoid cell cultures derived from the bone marrow of five humans with various forms of leukemia. Cell cultures were inoculated with BVV by mixing freshly trypsinized cells with an undiluted cell-free BVV preparation. After 2 mo of subcultivation, foci of altered cells suggestive of malignant transformation were noted. These foci were not present in noninoculated cultures. Both control and inoculated cultures had limited life-spans and could not be developed into continuous transformed cell lines. BVV genome functions could be demonstrated in the inoculated cells by immunofluorescence using a reference BVV serum, by the presence in the supernatant culture fluid of reverse transcriptase with a preference for Mg^{2+} ions, and by electron microscopic detection of cell-associated virus particles in one infected culture. However, infectious BVV could not be rescued. Compared with leukemic bone marrow cultures, normal human embryonic kidney and spleen tissue could not be infected with BVV. These findings indicate that BVV may play a role in either malignant or slow virus diseases in man and that exposure of genetically predisposed individuals could result in latent infection. Furthermore, the Mg^{2+} preference of the reverse transcriptase indicates that BVV differs from bovine syncytium virus and is closely related to Mason-Pfizer monkey virus and sheep visna virus. (20 refs)

78-2827 **Malignant Conversion of Shope Papillomas and Associated Changes of Serum Ceruloplasmin in Domestic Rabbits.** (Eng) Seto, A. (Dept. Microbiology, Faculty Medicine, Kyoto Univ., Kyoto 606, Japan); Tokuda, H.; Ito, Y. *Proc Soc Exp Biol Med* 157(4): 694-696; 1978.

Quantitative and qualitative changes of serum ceruloplasmin associated with the malignant conversion of Shope papillomas to squamous cell carcinomas were determined. The papillomas were induced in neonatal domestic rabbits by id injection of Shope papilloma virus, and they were converted into squamous cell carcinomas after a lapse of a year or more. Serum copper level before death due to malignancy was elevated two to six times compared with the level at 4 mo of age. Disk electrophoresis analysis of the serum showed that ceruloplasmin activity was manifested as single and double bands before and after malignant conversion, respectively. In one rabbit, the serum copper level was elevated twice at parturition and four times at malignant conversion compared with that of normal serum. At parturition, only a single band of ceruloplasmin appeared upon disk electrophoresis. The elevated level dropped to normal (68 μg/deciliter) at 1 mo after total tumor resection. The presence of two bands of ceruloplasmin activity in the malignant sera could be due to two distinct isozymes of ceruloplasmin. If this speculation is confirmed, the presence of ceruloplasmin isozymes could be used as a marker for the malignant conversion of benign tumors. (11 refs)

78-2828 **Characterization of Two Types of Human Papillomaviruses in Lesions of Epidermodysplasia Verruciformis.** (Eng) Orth, G. (Unite de Recherches sur l'Etiologie Virale des Cancers humains, Inst. Gustave-Roussy, Villejuif, France); Jablonska, S.; Favre, M.; Croissant, O.; Jarzabek-Chorzelska, M.; Rzesa, G. *Proc Natl Acad Sci USA* 75(3): 1537-1541; 1978.

Human papillomaviruses (HPV's) found in the lesions of 11 patients (5 men, 6 women, aged 7-45 yr) with epidermodysplasia verruciformis (EV) were compared to HPV type 1 (HPV-1) and HPV type 2 (HPV-2) previously characterized in plantar and common warts, respectively. The patients had had EV for 1-42 yr. Complementary RNA's (cRNA's) to HPV-1, HPV-2, and to the prototype viruses from two EV patients (1 and 2) were used in cRNA-DNA filter hybridization experiments. No sequence homology was detected between HPV-1 or HPV-2 DNA's and DNA's obtained from the 11 EV HPV isolates. Furthermore, with the cRNA's from patients 1 and 2, EV DNA fell into two groups showing little, if any, sequence homology. A lower extent of annealing was observed for the DNA's of some isolates showing a genetic heterogeneity within each of the two groups. Almost no antigenic cross-reaction was detected by immunodiffusion or indirect immunofluorescence tests, either between EV HPV's and HPV-1 or HPV-2, or between the HPV's of patients 1 and 2. Viruses related to the HPV of patient 1 were preferentially associated with flat wartlike EV lesions, and they were found in lesions from five patients bearing multiple flat warts. Viruses related to the HPV of patient 2 were found in the morphologically distinct lesions (red spots) present in some EV patients. It is suggested that these two types of HPV be labeled HPV-3 and HPV-4, respectively. Malignant conversion was noted in 3 patients with HPV-4, 1 with both HPV-3 and HPV-4, and 1 with HPV-3. (23 refs)

78-2829 **Characterization of a DNA-Protein Complex and Capsomere Subunits Derived from Polyoma Virus by Treatment with Ethyleneglycol-bis-N,N′-tetraacetic Acid and Dithiothreitol.** (Eng) Brady, J. N. (Div. Biology, Kansas State Univ., Manhattan, KS, 66506); Winston, V. D.; Consigli, R. A. *J Virol* 27(1): 193-204; 1978.

Polyoma virus was purified from lysates of infected mouse embryo and kidney cells. Treatment of the virions with ethyleneglycolbis-N,N′-tetraacetic acid (EGTA) and dithiothreitol (DTT) at pH 8.5 resulted in their dissociation into a DNA-protein complex and individual structural capsomere subunits. The sedimentation value of the DNA-protein complex in sucrose gradients was approx 48S, and it had a density of 1.45 g/cm³ in equilibrium CsCl gradients. Alkaline sucrose analysis of the DNA in the complex demonstrated that approx 75% of it was component 1. The proteins associated with the DNA were dissociated by treatment with NaCl or the anionic detergent Sarkosyl. VP1 and the histone proteins VP4-7 were the major proteins associated with the DNA. Treatment of the DNA-protein complex with alkaline pH resulted in the specific removal of VP1. Electron microscopy of the 48S DNA-protein complex demonstrated that it was a tightly coiled structure slightly larger than the intact virion. Treatment of the complex with NaCl or pH 10.5 buffer resulted in the loss of protein and subsequent loosening of the DNA-protein complex with the DNA becoming visible. The capsomere subunits released as a result of the EGTA-DTT treatment sedimented as 18S, 12S, and 5S subunits in sucrose gradients. Electrophoretic analysis of the isolated capsomeres demonstrated that VP1, VP2, and VP3 were present in each species, although the ratios of the proteins varied. In addition to the structural proteins, histones VP4-7 were found to be predominantly associated with the 5S capsomere subunit. (31 refs)

78-2830 **In Vitro Recombinant DNA Technology for Mapping Animal Virus Mutations (Meeting Abstract).** (Eng) Miller, L. K. (Dept. Bacteriology and Biochemistry, Univ. Idaho, Moscow, ID, 83843). *Miami Winter Symp* 14: 265; 1977. (1 ref)

78-2831 **Restriction to the Cell Nucleus of Virus-induced Host RNA's in a Rat Kidney Tumor Induced by Polyoma Virus.** (Eng) Shearer, R. W. (Issaquah Group Health and Environmental Res., 1595 N.W. Gilman Blvd., Issaquah, WA, 98027). *J Natl Cancer Inst* 60(6): 1383-1385; 1978.

A hybridization competition assay showed that the RNA transcripts of repetitive DNA of WF rat kidney, which were derepressed during transformation by polyoma virus, were not transported to the cytoplasm in the tumor cells. Transcripts of repetitive DNA found in the normal cell nucleus were all transported to the cytoplasm in the tumor cells, including those restricted to the nuclei in the normal cells. The results are contrasted with those of chemical carcinogenesis in which there is no derepression of cellular gene families. (9 refs)

78-2832 **Elevation of Alkaline Endodeoxyribonucleases in Nuclei of Polyoma Virus-infected Mouse Embryo Fibroblasts (Meeting Abstract).** (Eng) Goodwin, R. G. (Dept. Biochemistry, Univ. California, Riverside, CA, 92521); Sei, K. S.; Karu, A. E. *Fed Proc* 37(6): 1413; 1978. (no refs)

78-2933 **Electron Microscopic Evidence for Splicing of SV40 Late mRNAs.** (Eng) Bratosin, S. (Dept. Genetics, Weizmann Inst. Science, Rehovot, Israel); Horowitz, M.; Laub, O.; Aloni, Y. *Cell* 13(4): 783-790; 1978.

RNA displacement loops (R loops) were formed when poly-(A)-containing simian virus 40 (SV40) cytoplasmic RNA was hybridized with linear double-stranded SV40 DNA. Analysis of the R loops by electron microscopy confirmed the conclusions of biochemical studies that the leader sequences at the 5′ ends of the 16S and 19S late messenger RNA's (mRNA's) are not coded immediately adjacent to the main portions c the mRNA's. These data are consistent with either segmentation of the leaders or heterogeneity of their lengths. Measurements of the R-loop structures yielded the locations, on th physical map of SV40 DNA, of the bodies and leaders of th 16S and 19S late mRNA's plus the lengths of the bodie leaders, and the corresponding intervening DNA sequence (27 refs)

78-2834 **Exogenous DNA Transcription in Cells wi Their Native DNA Inhibited. III. Ribosom Changes Induced by Exogenous DNA.** (Eng) Lopez-Burill S. (Dept. Biology and Biochemistry Cancer, Instituto N cional de Oncologia, Ciudad Universitaria, Madrid-3, Spain Valladares, Y.; Alvarez-Rodriguez, Y.; Alvarez-Noves, *Rev Esp Oncol* 24(2): 287-294; 1978.

DNA transcription was studied in TC-SV40 cells (simia virus 40-induced hamster sarcoma established in vitro) i which native DNA replication had been blocked by incubation of the cells with 5′-bromodeoxyuridine (BUdR DNA isolated from Ehrlich ascites cancer (EAC) ce was injected into TC-SV40 cells. The cells were label by incubating them in the presence of ^{14}C-prote hydrolysate. Polyribosomes were isolated from e ponentially growing cells, and their optical densit radioisotopic activity, and ultrastructure were studie Logarithmically growing TC-SV40 cells and EAC ce showed a characteristic distribution of ribosom When the BUdR-blocked TC-SV40 cells were inoc lated with EAC cell DNA, there was an increase monoribosomes, an almost complete disappearance of dimers, and a diminution of protein synthesis. Thus, the ribos mal distribution of the TC-SV40 cells was changed to a pa tern typical of that for EAC cells. (6 refs)

78-2835 **Transfection of Permissive Monkey Cells wi Restriction Endonuclease-derived Fragments SV40 DNA. II. Rescue of SV40 Virions by Cell Fusion a Transfection (Meeting Abstract).** (Eng) Moyer, M. (Trini Univ., San Antonio, TX); Moyer, R.; Gerodetti, M.; Lip tich, G. *Miami Winter Symp* 14: 263; 1977. (2 refs)

78-2836 **A Single Cleavage of Simian Virus 40 (SV4 DNA by a Site Specific Endonuclease fro** *Thermus aquaticus, Taq* I. (Eng) Sato, S. (Mitsubis Kasei Inst. Life Sciences, Minamiooya, Machida, Tok 194, Japan). *J Biochem (Tokyo)* 83(2): 633-63 1978.

A site specific endonuclease from *Thermus aquaticus, Taq* cleaved simian virus 40 (SV40) DNA at a single site. Th cleavage site was localized on the physical map by double digestions using the previously characterized fragments produced by digestion with *Hae* II, *Hae* III, *Alu* I, *Hha* I, *Hinf* I, or *Bst* I followed by acrylamide gel electrophoresis. The exact *Taq* I site was estimated from the *Hae* III/*Taq* I digestion to be located on the (*Hae* III)-A fragment 135 nucleotide pairs from the left end of (*Hae* III)-B. This site corresponds to the position that is 56.5% of the unit length from the *Eco* RI site, and it is very close to the position where early and late messenger RNA start to be transcribed in opposite directions. (3 refs)

78-2837 **Transfection of Permissive Monkey Cells with Restriction Endonuclease-derived Fragments of SV40 DNA. I. Transformation and Superinfection Properties of Recipient Cells (Meeting Abstract).** (Eng) Moyer, R. C. (Trinity Univ., San Antonio, TX); Moyer, M. P.; Hurtado, H. *Miami Winter Symp* 14: 261; 1977. (no refs)

78-2838 **Evidence for "Splicing" of SV40 16S mRNA.** (Eng) Haegeman, G. (Lab. Molecular Biology, Ledeganckstraat, 35, B-9000 Ghent, Belgium); Fiers, W. *Nature* 273(5657): 70-73; 1978.

The major simian virus 40 (SV40)-specific messenger RNA (mRNA), which sediments at 16S, was characterized by comparing its fingerprint with the nucleotide sequence of the DNA. The results indicate that the 16S mRNA is coded for by at least two separate regions on the genome. The 5′-leader sequence is about 180 nucleotides in length and is transcribed from the region 0.72 to 0.76 on the standard map. The body of the mRNA starts, at most, 40 nucleotides before the initiation codon for the VP1 protein and contains the whole structural VP1 gene, followed by the untranslated 3′-terminal end. It thus extends clockwise from coordinates 0.94 to 0.17. There is no evidence that the two parts of the RNA molecule are joined by anything other than a normal phosphodiester linkage. It is not known whether the splicing occurs during transcription or is the result of a subsequent excision-ligation event, but the latter mechanism seems more likely. The concept of splicing in the formation of eukaryotic mRNA may partly explain the complex processing events undergone by heterogeneous nuclear RNA. (38 refs)

78-2839 **Comparative Behavior of Simian Virus 40 T-Antigen and of Tumor-specific Surface and Transplantation Antigens During Partial Purification.** (Eng) Luborsky, S. W. (NCI, NIH, Bethesda, MD, 20014); Chang, C.; Pancake, S. J.; Mora, P. T. *Cancer Res* 38(8): 2367-2371; 1978.

Simian virus 40-specific T antigen was extracted from SV AL/N mouse embryo tissue culture cells by treatment with Triton X-100 detergent. The extracts contained tumor-specific transplantation antigen (TSTA) and tumor-specific surface antigen. After purification by ammonium sulfate precipitation and diethylaminoethylcellulose and phosphocellulose column chromatography, the extracts were assayed for the three antigens. T antigen, TSTA, and much of the tumor-specific surface antigen copurified through all the purification steps. This finding supports previous suggestions of the close homology among the protein species carrying these three antigenic determinants. The antibody-mediated cytolytic assay appeared to detect a new type of cell-surface antigen that is different from T antigen and TSTA. Two antigenic fractions were obtained from the phosphocellulose column that had tumor-specific surface antigen activity, but one of these did not have T-antigen or TSTA activities. (30 refs)

78-2840 **Kinetics of Appearance and Loss of S Antigen in Cells after Abortive or Lytic Infection with SV40.** (Rus) Matveeva, V. A. (Cancer Res. Center, Moscow, USSR); Klyuchareva, T. E.; Deichman, G. I. *Vopr Virusol* (3): 314-317; 1978.

A mixed hemadsorption assay was used to evaluate the kinetics of the appearance and loss of surface (S) antigen in hamster cell and green monkey kidney cell cultures after abortive and lytic infection with simian virus 40. S antigen could be detected in abortively infected hamster cells growing in monolayer; culturing of the hamster cells led to the rapid loss of antigen (after 2-3 passages). S antigen persisted in both stationary and proliferating cultures of green monkey cells. (7 refs)

78-2841 **A Growth Factor for SV40 Virus-Transformed Fibroblasts (SV3T3) from Isolated Rat Hepatocytes (Meeting Abstract).** (Eng) Schuler, M. (M. S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA, 17033); Feldhoff, R. C.; Jefferson, L. S.; Lipton, A. *Proc Am Assoc Cancer Res* 19: 220; 1978. (no refs)

78-2843 **Uptake of Low Molecular Weight Substances by SV40-Transformed 3T3 Cells Is Invariant**

with Growth Rates in the Presence and Absence of Serum. (Eng) Bush, H. (Cancer Res. Campaign Dept. Medicine Oncology, Christie Hosp. and Holt Radium Inst., Manchester, England, M20 9BX); Shodell, M. *Exp Cell Res* 114(1): 27-30; 1978.

The uptake of 2-deoxy-D-glucose (DG) and α-aminoisobutyric acid (AIB) was measured in simian virus 40-transformed 3T3 cells growing in the presence and absence of serum to determine whether changes in proliferative behavior are due to changes in the rate of transport of low-mol-wt substances. Changes in the rates of growth and of DNA synthesis were not accompanied by parallel changes in the uptake of DG and AIB. Thus, nutrient supply is not a major regulatory factor in determining the transformed cell growth rate. (13 refs)

78-2844 **A Study of Cultured Fetal and SV40-transformed Chinese Hamster Kupffer Cells.** (Eng) Clark, J. M. (Dept. Medical Cell Genetics, Medical Nobel Inst., Karolinska Institutet, S-104 01 Stockholm, Sweden); Pateman, J. A. *Exp Cell Res* 114(1): 47-56; 1978.

The characteristics of normal and simian virus 40 (SV40)-transformed adult and fetal Chinese hamster Kupffer cells in culture were compared. The study included 65 SV40-transformed adult Kupffer cell lines (SV40-ACHK), 4 SV40-transformed fetal Kupffer cell lines (SV40-FCHK), and 24 untransformed fetal Kupffer cell lines. Both adult and fetal Kupffer cell lines expressed Kupffer cell functions for a considerable period in culture. Cloned SV40-transformed Kupffer cell lines exhibited properties associated with neoplastic transformation in culture: (1) SV40 tumor antigen; (2) irregular growth pattern; (3) growth in agar suspension culture; (4) growth in medium containing a low serum concentration; and (5) high saturation density. Prior to SV40 transformation, all adult and fetal Kupffer cell lines possessed peroxidase, microsomal heme oxygenase (MHO), and phagocytic activities. After 97 population doublings (PD), normal fetal cell lines had lost phagocytic activity but had retained MHO and peroxidase activities. By 8-9 PD after infection with SV40, none of these activities could be detected in the transformed cell lines. Some of the transformed cell lines remained diploid for at least 80 PD after infection. It is concluded that this cell culture system makes it possible to compare adult, fetal, and SV40-transformed cell lines of defined genetic and epigenetic origin. (31 refs)

78-2845 **Tumor Induction in Newborn and Adult Syrian Hamsters Infected with SV40 Temperature-sensitive Mutants.** (Eng) Deichman, G. (Cancer Res. Center, Acad. Medical Sciences, Moscow, USSR); Kashkina, L.; Rapp, F. *Intervirology* 10(2): 120-124; 1978.

Newborn and adult Syrian hamsters were inoculated with
wild-type simian virus 40 (SV40) and its temperature-sens
tive (*ts*) mutants A30, A209, A239, B201, and BC21
Wild-type SV40 and *ts* B201 were highly oncogenic for nev
born but not adult animals; *ts* A239, *ts* A30, and *ts* BC21
also induced tumors in some adult hamsters. Unexpectedl
the number of tumors induced by *ts* A209 and *ts* A239 i
newborn animals was very low. Tumor frequency was als
low in adults infected with *ts* A30, *ts* A239, and *ts* BC21
The duration of the latent period of tumors induced in adu
animals was the same as that in the newborns. The data o
tained are discussed in connection with the defectiveness
the mutants in inducing tumor-specific transplantation ant
gen activity in hamster cells. (15 refs)

Sensitization Against SV40 Tumors (Meetin
Abstract). (Eng) Blasecki, J. W. (Winter Res. Lab., Mou
Sinai Medical Center, Milwaukee, WI, 53233); Houston, K
J. *Fed Proc* 37(6): 1452; 1978. (no refs)

78-2847 **Cell Adhesion and Cell Surface Topography**
Aggregates of 3T3 and SV40-Viru
Transformed 3T3 Cells. Visualization of Interior Cells
Scanning Electron Microscopy. (Eng) Gershman, H. (Dep
Biochemistry and Biomedical Engineering, Case Western R
serve Univ., Cleveland, OH, 44106); Rosen, J. J. *J Cell Bi*
76(3): 639-651; 1978.

A technique for exposing the interior of aggregates of cu
tured cells was developed and used to examine, by scanni
electron microscopy, cell morphology and cell contact ultra
tructure in the interior of aggregates of BALB/c 3T3 a
simian virus 40 (SV40)-transformed 3T3 cells. The 3T3 ce
made initial intercellular contact by microvillar process
Over a period of 3-8 hr, some of these microvillar conta
were replaced by broader projections. In contrast, the SV4
transformed cells made initial intercellular contact
blebs or blunt projections that were also broadened a
extended over 3-8 hr. In both 3T3 and SV40-3T3 ce
the surfaces of cells forming the outer layer of t
aggregate resembled the surfaces of single cells fixed
suspension, regardless of how long the aggregates h
been cultured. These cells were covered with ma
cellular processes and were roughly hemispherical
profile. The surface of the internal cells of the aggrega
lost many of their cellular processes and develop
smooth patches, and many became irregular in shape. Th
smooth morphology was also observed on the surfaces of t
interior peripheral cell layer. It is concluded that the stabi
zation of adhesive contacts is a slow process that takes at lea
3-8 hr and that the surfaces of the outer layer of the periphe
al cells differ significantly from the those of the interior cell
Clear differences in surface topography exist between no
malignant 3T3 cells and their malignant SV40 transforman
(22 refs)

78-2848 **Cellular Transformation In Vitro by the Transfer of Isolated Metaphase Chromosomes.** (Fre) Cassingena, R. (Institut de Recherches scientifiques sur le cancer [C.N.R.S.], B.P. no. 8, 94800 Villejuif, France); Suarez, H. G.; Lavialle, C. *C R Acad Sci [D] (Paris)* 285(16): 1603-1606; 1977.

Metaphase chromosomes isolated from HeLa cells or human sc tissue cells transformed in vitro by simian virus 40 (SV40) were used to infect (transfect) cultures of line 3T3-4E murine cells and line 809 normal diploid human cells. The recipient cells were trypsinized and seeded, 24 hr after initial culture, in soft-agar medium containing 20% bovine serum or in liquid medium containing 1% serum. The infected mouse cells grew in soft-agar medium, indicating transformation had occurred, but continuous passage of these cells was not achieved. The infected human cells grew in both soft-agar and liquid medium, and up to 10 in vitro cell passages were achieved. The presence of SV40 tumor antigen on the human SV40-transformed cells was considered to be evidence of transformation by the chromosomes from these cells. This antigen was detected by immunofluorescence in all passages of the human cells infected with chromosomes from the SV40-infected cells. (16 refs)

78-2849 **SV40 Virus Interaction with Permissive Host Cells in Culture (Meeting Abstract).** (Eng) Gershey, E. L. (Rockefeller Univ., New York, NY, 10021). *In Vitro* 14(4): 368; 1978. (no refs)

78-2851 **A Virus-producing Cell Line Developed by Transformation of Human Parapharyngeal Cells with SV40.** (Eng) Rafferty, K. A. (Dept. Anatomy, Sch. Basic Medical Sciences, Univ. Illinois Medical Center, 1853 W. Polk St., Chicago, IL, 60612); Ruben, R. L.; Young, S. K. *In Vitro* 14(2): 227-235; 1978.

Normal cultures of epithelial appearance were initiated by trypsinization of a surgically resected, histologically normal parapharyngeal cyst. Cellular morphology was consistent with derivation from the stratified squamous epithelium of the cyst or from vascular endothelium. Infection with simian virus 40 (SV40) at a dose of 44 plaque-forming units per cell resulted in the appearance of grossly visible transformed foci within 25 days. The transformants were also epithelioid in appearance; they grew vigorously for 22-50 population doublings (23-32 subcultures) and then became quiescent. Virus was detectable at all stages by both direct isolation (cell extracts) and cocultivation with permissive cells. In two sublines in which selection for rapidly growing cell types occurred, virus was detected only by cocultivation. In no case was SV40 detected by electron microscopy, indicating that few cells were producers or that cells produced very few particles. It would appear from these studies that focus isolation tends to select against producer lines, whereas serial subculture at high density is more likely to result in development of producer lines. (27 refs)

78-2852 **Screening of Human Brain Tumors for SV40-related T Antigen.** (Eng) Tabuchi, K. (Univ. Colorado Medical Center, Div. Neurosurgery, Denver, CO 80262); Kirsch, W. M.; Low, M.; Gaskin, D.; Van Buskirk, J.; Maa, S. *Int J Cancer* 21(1): 12-17; 1978.

Thirty-nine human brain tumors were screened for the presence or absence of simian virus 40 (SV40) tumor (T) antigen by direct and indirect immunoperoxidase techniques. The tumors consisted of 12 glioblastomas, 5 astrocytomas, 1 ependymoma, 1 oligodendroglioma, 3 medulloblastomas, 1 neurinoma, 1 plexus papilloma, 10 meningiomas, 1 hemangioendothelioma, 1 angiofibroma, and 3 metastatic cancers. Only the ependymoma and the plexus papilloma had a positive immunoperoxidase reaction for the antigen both in vivo and in vitro. No staining was detected in the nuclei of tumor cells treated with either anti-SV40 V (anti-SV40 capsid antigen) or anti-human IgG conjugates; no positive staining was present after the tumors were heated to 55 C for 30 min. Nuclear extracts from the ependymoma also demonstrated nuclear antigen. Subcultures of these tumors at the sixth transfer were checked by an independent laboratory and found to be negative for T antigen by immunofluorescent screening. It is suggested that long-term subculture resulted in selective overgrowth of non-T-expressing cells, or the immunofluorescent test was not as sensitive as the immunoperoxidase test. (30 refs.)

78-2855 **Characterization of Herpesvirus Saimiri-induced DNA-directed DNA Polymerase (Meeting Abstract).** (Eng) Ebert, P. S. (NIH, Bethesda, MD, 20014); Vande Woude, G. *Proc Am Assoc Cancer Res* 19: 231; 1978. (no refs)

78-2856 **Tumour Induction with DNA of Oncogenic Primate Herpesviruses.** (Eng) Fleckenstein, B. (New England Regional Primate Res. Center, Harvard Medical Sch., 1 Pine Hill Drive, Southborough, MA, 01572); Daniel, M. D.; Hunt, R. D.; Werner, J.; Falk, L. A.; Mulder, C. *Nature* 274(5666): 57-59; 1978.

The tumorigenicity of the DNA of *Herpesvirus saimiri* and *H. ateles* was determined in cotton-top marmoset monkeys. *H. saimiri* DNA (0.05-10 μg) was slowly injected iv, ip, or im into 14 marmosets. Three animals died 60-85 days later. Microscopic examination confirmed lymphoblastic-type malignant lymphoma with extensive invasion and replacement of the lymph nodes, spleen, bone marrow, thymus, liver, and kidney. All reisolation trials, except one, were successful. Four marmosets were infected similarly with 20 μg *H. ateles* DNA. One monkey died after 97 days with clinical and gross features of malignant lymphoma. The lesion resembled that of *H. ateles* in this species except that there was extensive necrosis of the lymphocytic follicles in the spleen and lymph nodes. Attempts to isolate virus or to demonstrate an immune response to structural viral antigens were unsuccessful. However, DNA-DNA hybridizations showed that at least 0.013% of liver DNA and 0.015% of spleen DNA, extracted from autopsy material, hybridized with radioactive L DNA of *H. ateles* (equal to at least 7 viral DNA copies/diploid liver cell, 8 copies/spleen cell). [L DNA is a region of unique DNA (36%-38% guanine + cytosine, mol wt 71,800,000) inserted between 2 termini of repetitive DNA with variable lengths.] The striking difference in incubation period between these lymphomas and those caused by infectious virus particles (60-97 vs 30 days) shows that transformed cells or biologically active DNA can persist in the organism over prolonged periods. The ability of herpesvirus DNA to induce tumors indicates that DNA molecules of large size can be incorporated into the cells of living organisms in higher mammalian species. (16 refs)

78-2857 **Experimental Infection of *Callithrix jacchus* Marmosets with *Herpesvirus ateles*, *Herpesvirus saimiri*, and Epstein Barr Virus.** (Eng) Ablashi, D. V. (NCI, Room A-906, Landow Building, 7910 Woodmont Ave., Bethesda, MD, 20014); Pearson, G.; Rabin, H.; Armstrong, G.; Easton, J.; Valerio, M.; Cicmanec, J. *Biomedicine [Expres* 29(1): 7-10; 1978.

The effect of an ip injection of *Herpesvirus ateles* (HVA strain 73, *Herpesvirus saimiri* (HVS), or Epstein-Barr viru (EBV) on common marmosets (*Callithrix jacchus*) was dete mined. HVA induced tumors containing several types cells, including lymphocytes, plasmacytoid lymphocytes, hi tiocytes, polymorphonuclear WBC, and giant cells characte istic of the Reed-Sternberg cells in Hodgkin's disease. HV and EBV did not induce tumors, but HVS was present in th lymphocytes and it elicited a strong antibody response. EB elicited only a variable antibody response. The common ma moset probably requires cofactors for the development of tu mors following EBV and HVS infection and is thus a mod complementary to the cotton-topped marmoset, which do not require these cofactors. (20 refs)

78-2858 **Measurements of the Molecular Size of th Simian Virus 40 Large T Antigen.** (Eng) Griffi J. D. (Div. Medical Oncology, Sidney Farber Cancer Ins Boston, MA, 02115); Light, S.; Livingston, D. M. *J Vir* 27(1): 218-226; 1978.

The mol wt of the large simian virus 40 (SV40) tumor (antigen was estimated by sodium dodecyl sulfa (SDS)-polyacrylamide gel electrophoresis, random-co chromatography in guanidine hydrochloride, and sediment tion-velocity analysis in a density gradient. In view of th strong theoretical basis for the guanidine method and th agreement with the sedimentation data, these findings su gest that the mol wt of the SV40 protein is 75,000-80,00 daltons (75K-80K) rather than 94K-100K. Therefore, co siderably less than the entire early region of SV40 is require to encode it. This size estimate is in accord with earlier r sults, which revealed a normal-size T antigen in cells infecte with viable deletion mutants lacking as much as 10% of th early region. Large T antigen isolated from an SV40-tran formed human fibroblast cell line and from a lytically infec ed African green monkey kidney cell line migrated in parall as a single 94K polypeptide in SDS-polyacrylamide gel However, both proteins had an approx mol wt of 75K by th other two methods. (57 refs)

78-2859 **An In Vitro Transformation Assay for SiSV and HL23V Using Feline Embryonic Fib blasts (40044).** (Eng) Markham, P. D. (Dept. C Biology, Litton Bionetics, Inc. Bethesda, MD, 2001 Dodge, W.; Salahuddin, S. Z.; Gallagher, R. E. *Pr Soc Exp Biol Med* 157(2): 312-318; 1978.

The focus-forming ability of simian sarcoma virus (SiSV and HL23V, a virus isolated from the cultured periphe blood and bone marrow WBC of a patient with acute m logenous leukemia, was determined in feline embryo fibroblasts (FEF), normal rat kidney cells, rat embryo fibroblasts, and several cultures of primate origin. The findings for these viruses were compared to those for baboon endogenous virus (BaEV) and gibbon ape leukemia virus (GaLV). SiSV-1 and HL23V were able to induce foci in all cell lines tested. GaLV and BaEV showed no indication of transformation. SiSV-1, HL23V, and GaLV were able to replicate in all cell lines; BaEV did not replicate in any of the lines. With FEF cells, foci were completely developed and ready for counting by the third or fourth day after infection, but the other lines required 7-10 days for max focus development. Transformation was 2-100 times more efficient with FEF cells than with cells normally used for SiSV-1 transformation. (25 refs)

78-2860 **Antigenic Relationship of Human Foamy Virus to the Simian Foamy Viruses.** (Eng) Nemo, G. J. (Lab. Central Nervous System Studies, Intramural Res. Program, Natl. Inst. Neurological and Communicative Disorders and Stroke, Bethesda, MD, 20014); Brown, P. W.; Gibbs, C. J.; Gajdusek, D. C. *Infect Immun* 20(1): 69-72; 1978.

A foamy virus previously isolated from a human nasopharyngeal carcinoma was studied by reciprocal cross-neutralization and cross-immunofluorescent techniques to determine its antigenic relationship to the eight known simian foamy viruses (SFV). Cross-immunofluorescent screening indicated a two-way cross-reactivity between human foamy virus and SFV-6, SFV-7, and, to a lesser degree, SFV-1. In the cross-neutralization studies, a reciprocal cross-relationship was observed between human foamy virus and SFV-6, but not between the human virus and SFV-7 or SFV-1. In a seroepidemiological survey, neutralizing antibody to the human foamy virus was not detected in the sera of 14 animal caretakers or 24 laboratory personnel who routinely handled a wide variety of nonhuman primates. It is concluded that the human isolate most probably represents a variant strain of SFV-6. (6 refs)

78-2861 **The Phosphodiesterase I-Alkaline Phosphatase System in Herpes Simplex Virus (Type 1) Transformed Hamster Cells. Biochemical and Biological Properties (Meeting Abstract).** (Ger) Schneider, D. (Abteilung fur Exptl. Virologie, Inst. Medizinische Mikrobiologie, Univ. Mainz, Hochhaus am Augustusplatz, D-6500 Mainz, W. Germany). *Hoppe Seylers Z Physiol Chem* 359(3): 317-318; 1978. (6 refs)

78-2862 **Infectious Mononucleosis, Herpes Simplex Infection, and Diffuse Lymphoma in a Renal Transplant Recipient.** (Eng) Briggs, J. D. (Renal Unit, Univ. Dept. Surgery, Western Infirmary, Glasgow, G11 6NT, Scotland); Hamilton, D. N.; MacSween, R. N.; Pennington, T. H. *Transplantation* 25(4): 227-228; 1978.

A 22-yr-old girl developed diffuse lymphoblastic lymphoma 4 yr after receiving a kidney transplant. At the time of presentation, herpes simplex lesions were present around the patient's mouth and vulva; she also had infectious mononucleosis and an Epstein-Barr virus infection. It is not known if the lymphoma preceded or followed the viral infections. (5 refs)

78-2863 **High Incidence of Virus Isolation from Donor and Recipient Tissues Associated with Renal Transplantation.** (Eng) Orsi, E. V. (Biology Dept., Seton Hall Univ., South Orange, NJ, 07079); Howard, J. L.; Baturay, N.; Ende, N.; Ribot, S.; Eslami, H. *Nature* 272(5651): 372-373; 1978.

Tissues from donor kidneys (10), livers (2), or spleens (2) and from 15 kidney recipients were examined by immunofluorescent staining for herpes simplex virus types 1 and 2 (HSV1 and HSV2) and cytomegalo-virus (CMV). HSV-1 was isolated from 1/14 donors and 3/15 recipients, HSV-2 from 5 donors and 7 recipients, human CMV from 11 donors and 12 recipients. Isolation of all three viruses from the same individual occurred in one donor and one recipient. The most frequent combination was HSV-2 and CMV. The frequency of CMV isolation agreed with the incidence of infection found in serological studies, but the rates of HSV-1 and HSV-2 isolation were unexpectedly high. The isolation of herpesvirus from tissue donors without apparent herpetic lesions may complicate attempts to relate these viruses to neoplasia and other diseases. (15 refs)

78-2864 **Relationship Between HSV-2-Antigen and Colpocytological Findings. (Meeting Abstract).** (Ger) Gorcs, J. (Sorhaz U. 4, H-7621 Pecs, Hungary). *Fortschr Med* 96(7): 350; 1978. (no refs)

78-2865 **Properties of Epstein-Barr Virus Transformed Woolly Monkey Lymphoblastoid Cell Lines.** (Eng) Andiman, W. A. (Dept. Pediatrics, Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT, 06510); Miller, G. *Proc Soc Exp Biol Med* 157(3): 489-493; 1978.

The establishment of a lymphoblastoid cell line following in vitro transformation of woolly monkey WBC by the B95-8 strain of Epstein-Barr virus (EBV) is reported. Woolly monkey peripheral blood lymphocytes were relatively resistant to in vitro transformation by EBV: only 14/145 virus-exposed WBC cultures resulted in cell lines. No lines were derived without in vitro exposure to virus. Transformation frequency could not be increased by exposing the WBC to mitogens, depleting the number of T cells, or exposing the cells to virus after several days in culture. Almost half the lymphocytes in fresh blood had a receptor for IgFc, and 60%-90% of continuously cultured cells expressed receptors for both rabbit and human IgFc. On the lymphoblastoid lines, however, the IgFc receptor was qualitatively different from that induced by herpes simplex virus, which could be detected with rabbit but not human Ig. Monkeys inoculated with cell-free virus and autologous transformed cells showed no evidence of infection. Thus, although woolly monkey cells can be transformed in vitro by EBV, they are not oncogenic when replaced in the autologous host. (20 refs)

78-2866 **Heterogeneity of Epstein-Barr Virus. III. Comparison of a Transforming and a Nontransforming Virus by Partial Denaturation Mapping of Their DNAs.** (Eng) Delius, H. (European Molecular Biology Lab., 6900 Heidelberg, W. Germany); Bornkamm, G. W. *J Virol* 27(1): 81-89; 1978.

The DNA's of transforming (B95-8) and nontransforming (P3HR-1) Epstein-Barr virus (EBV) strains were compared by partial denaturation mapping. The former virus was derived from EBV-transformed marmoset lymphocytes, the latter from a Burkitt's lymphoma. B95-8 viral DNA showed a homogeneous denaturation pattern. In contrast, P3HR-1 viral DNA was heterogeneous: it contained at least two classes of molecules, Groups A and B, which were present in a ratio of about 2:1 to 3:1. No evidence was obtained that molecules from Groups A and B contained identical sequences present in different orientations, as described for herpes simplex viral DNA. Most of the sequences present in B95-8 and in P3HR-1 viral DNA Group A could be correlated by assuming that different sequences, about 12,000 base pairs long, were inserted or deleted, respectively, at different positions of both viral genomes. (23 refs)

78-2867 **Inhibition of DNA Metabolism in Human B Lymphocytes by a Substrain of Epstein-Barr Virus (P3HR-1): A Method for Virus Quantitation.** (Eng) Steinitz, M. (Dept. Tumor Biology, Karolinska Institutet, S-104 01 Stockholm, 60, Sweden); Bakacs, T.; Yefenof, E.; Klein, G. *Intervirology* 10(2): 125-131; 1978.

Pretreatment with the P3HR-1 substrain of Epstein-Barr virus (EBV) inhibited by approx 85% the DNA stimulation induced by *Staphylococcus aureus* in human B lymphocytes. In parallel experiments, the DNA stimulation induced by the transforming B95-8 substrain of EBV was almost completely inhibited by prior exposure to P3HR-1 virus. Phytohemagglutinin stimulation was inhibited only slightly but the DNA synthesis of continuously growing Raji cells was inhibited to a considerable extent. The degree of DNA inhibition was correlated with the induction of the EBV membrane, early, an
nuclear antigens in sensitive indicator cells. (14 refs)

78-2869 **Relationship Between Humoral Antibodies
Epstein-Barr Virus and Tumors of the Lyn
phoid System in Man.** (Rus) Mazurenko, N. P. (Cancer Re
Center, Moscow, USSR); Stepina, V. N.; Gurtsevich, V.
Yarymova, N. M.; Kaverzneva, M. M.; Lorie, Yu. I.; Kr
evsky, N. A.; Durnov, L. A.; Ermakov, E. S.; Probatova,
A.; Pokrovskaya, N. N. *Vestn Akad Med Nauk SSSR* (
60-71; 1977.

The level of antibodies against Epstein-Barr virus (EBV) w
assessed in sera of 28 clinically healthy children
14 yr), 69 children with various benign and maligna
tumors (neuroblastoma, Wilms' tumor, reticulosarcom
teratoblastoma, sarcoma of the soft tissues), 94 ad
patients with Hodgkin's disease and 55 adult patien
with various tumors of the lymphoid system. The
was no difference in the titer of humoral antibodi
against EBV between the healthy children (1:6
and children with benign (1:62) or malignant tumors (1:65
The patients with Hodgkin's disease had significantly i
creased antibody titers (1:150 in the patients wi
nodular-sclerous variant, 1:242 in mixed cellular varia
and 1:356 in the patients with lymphoid exhaustio
Simultaneously, the patients with all variants
Hodgkin's disease showed significant (almost two-
threefold) decrease of the indices of the T-cell i
munity. In spite of the marked tropism of EBV
the lymphoid tissues, the patients with tumors of t
lymphoid system showed no increase in the titer
antibodies against EBV. (50 refs.)

78-2870 **Lymphocytes Transformed by Epstein-Ba
Virus: Induction of Nuclear Antigen Reacti
with Antibody in Rheumatoid Arthritis.** (Eng) Alspaugh,
A. (Dept. Medicine, Univ. Louisiana Sch. Medicine, Ne
Orleans, LA); Jensen, F. C.; Rabin, H.; Tan, E. M. *J Exp M*
147(4): 1018-1027; 1978.

The indirect immunofluorescence test was used to detect t
presence, in several lymphocyte lines, of a nuclear antig
that would react with antibodies in the sera of patients wi
rheumatoid arthritis (RA). The lines tested included norm
and Epstein-Barr virus (EBV)-transformed human periphe

blood lymphocytes and established human (umbilical cord) and simian (cotton-topped marmoset, orangutan, baboon, and owl monkey) lymphocyte lines infected with EBV and related herpesviruses. The nuclear antigen reactive with antibody in the sera of RA patients could be induced in EBV-infected human lymphocytes. The EBV-infected cells did not react with normal human sera, and control uninfected cells did not react with RA sera. Simian cell lines that had been transformed by EBV contained the nuclear antigen reactive with RA sera, whereas human cord cells infected with herpesvirus papio and simian cell lines carrying herpeslike viruses were negative for this antigen. Although most cells containing RA-associated nuclear antigen also contained Epstein-Barr nuclear antigen (EBNA), there was a lack of complete concordance. The RA-associated nuclear antigen was differentiated from EBNA by immunofluorescence and immunodiffusion tests and by nuclear staining. The data do not indicate whether an etiological relationship exists between EBV infection and RA. (21 refs)

78-2871 **The Capacity of Lymphoblastoid Cells to Activate the Alternative Complement Pathway Is Correlated with Their Transformation by Epstein-Barr Virus (Meeting Abstract).** (Eng) McConnell, I. (MRC Group on Mechanisms on Tumour Immunity, Cambridge, England); Lachmann, P. J.; Lint, T.; Klein, G. *J Immunol* 120(5): 1787; 1978. (no refs)

78-2872 **Epstein-Barr Virus Related Antigens in Cultured Human Cancer Cells.** (Jpn) Inoue, J. (Dept. Surgery, Tokyo Medical Coll., Shinjuku-ku, Tokyo 160, Japan). *Tokyo Ika Daigaku Zasshi* 35(5): 771-782; 1977.

A total of 31 cultured cell lines from various types of human cancers (17 epithelial, 6 nonepithelial, 4 of neurogenic tumor origin, and 4 lymphoblastoid) were studied for the presence of the viral capsid antigen (VCA) and early antigen (EA) of Epstein-Barr virus (EBV). VCA-positive cells were detected only in the P$_3$HR-1, MK-Ly, and PC-5-Ly lymphoblastoid cell lines. EA-positive cells, however, were detected in the Raji and P$_3$HR-1 lymphoblastoid lines and in the OAT, PC-1, and PC-5 lines of pulmonary carcinoma origin. These findings suggest a possible role for EBV in the development of pulmonary carcinoma. (50 refs)

78-2873 **Partial Purification and Properties of the Epstein-Barr Virus-associated Nuclear Antigen.** (Eng) Baron, D. (Medizinische Universitaetsklinik, Otfried-Mueller-Strasse, D-74 Tubingen, W. Germany); Strominger, J. L. *J Biol Chem* 253(8): 2875-2881; 1978.

Epstein-Barr virus (EBV)-associated nuclear antigen (EBNA) was purified 85-fold from a nuclear pellet derived from an EBV-transformed B-lymphoblastoid cell line, and some of its properties were determined. The purification procedure consisted of five steps: preparation of extract, heating at 80 C in phosphate buffer, ammonium sulfate precipitation, preparative ultracentrifugation, and affinity chromatography on double-stranded DNA-cellulose. The most highly purified material contained a major polypeptide of 49,000 daltons together with several other polypeptides present in much smaller amounts; it is uncertain which of these is EBNA. The purified complement fixing antigen specifically blocked the anticomplement immunofluorescence assay for EBNA. Several properties indicate a close association of EBNA with chromatin: (1) precipitation of antigenic activity by phosphate buffer and subsequent thermal fractionation; (2) partial sensitivity of antigenic activity to DNase but not to RNase and restoration of activity by addition of calf thymus DNA; and (3) specific binding of EBNA to double-stranded DNA-cellulose. EBNA was unusually heat stable; no loss of antigenic activity was observed even after heating for 30 min at 80 C. This heat stability suggests that EBNA is either a single polypeptide chain or a homooligomer, because it is unlikely that all the different proteins of a heterooligomer would show this exceptional heat stability. (33 refs)

78-2874 **Persisting Oncogenic Herpesvirus Induced by the Tumour Promoter TPA.** (Eng) zur Hausen, H. (Inst. Virologie, Zum Hygiene, Univ. Freiburg, Freiburg, W. Germany); O'Neill, F. J.; Freese, U. K.; Hecker, E. *Nature* 272(5651): 373-375; 1978.

The effect of the cocarcinogen and tumor promotor 12-O-tetradecanoylphorbol-13-acetate (TPA: 20 nanograms/ml) on Epstein-Barr virus (EBV) production was studied in two producer cell lines [P3HR-I, of Burkitt's lymphoma (BL) origin, and B95-8, an EBV-transformed marmoset line of infectious mononucleosis origin] and two nonproducer cell lines (Raji BL cells and NC37 cells from a normal donor). TPA increased the number of antigen-positive cells in all four lines. Viral capsid antigen was increased in P3HR-I and B95-8, but only early antigen (EA) was induced in NC37 and Raji cells. Effective virus particle production in the producer line was demonstrated by electron microscopy. EA or VCA synthesis was also increased in 10 other EBV-transformed lymphoblastoid lines tested. Two baboon lines transformed by herpesvirus papio showed only a moderate antigen induction, but a T-cell line transformed by herpesvirus saimiri was efficiently induced after TPA treatment. The potential usefulness of P3HR-I and B95-8 cells for biological and immunologic studies of EBV is discussed. (14 refs)

78-2875 **DNA of Epstein-Barr Virus. III. Identification of Restriction Enzyme Fragments that Contain**

DNA Sequences which Differ among Strains of Epstein-Barr Virus. (Eng) Raab-Traub, N. (Section Infectious Diseases, Dept. Medicine, Univ. Chicago, Chicago, IL, 60637); Pritchett, R.; Kieff, E. *J Virol* 27(2): 388-398; 1978.

The HR-1, B95-8, and W91 strains of Epstein-Barr virus (EBV) were studied to identify the restriction enzyme fragments of the DNA of each of these strains that contain sequences not present in the other strains. The DNA's of the three strains differed in complexity. Sequences missing in the B95-8 strain were found in the *Eco*RI-C and -D and *Hsu* I-E and -N fragments of the HR-1 strain and in the *Eco*RI-C and *Hsu* I-D and -E fragments of the W91 strain. The HR-1 strain was missing DNA contained in *Eco*RI fragments A and J to K and *Hsu* I fragment B of the B95-8 strain and in the *Eco* RI-A and *Hsu* I-B fragments of the W91 strain. Available data suggest that the W91 strain contains all of the sequences present in both the B95-8 and HR-1 strains. These data studied in relationship to a linkage map of the restriction enzyme fragments of the DNA of B95-8 and W91 show that the additional DNA in these strains is in the region of overlap between *Eco*RI fragment A and *Hsu* fragment B of the E3V B95-8 and W91 DNA's. Indirect lines of evidence support the hypothesis that the DNA deleted in the HR-1 strain accounts for the inability of this strain to transform lymphocytes to lymphoblasts with indefinite growth in vitro. (29 refs.)

78-2876 **Epstein-Barr Virus Infection in Staff Treating Patients with Nasopharyngeal Carcinoma (Letter to Editor).** (Eng) Ho, H. C. (Medical and Health Dept., Inst. Radiology and Oncology, Queen Elizabeth Hosp., Kowloon, Hong Kong); Kwan, H. C.; Poon, Y. F.; Tse, K. C.; Ng, M. H. *Lancet* 1(8066): 710-711; 1978.

The IgA and IgG reactivities to the viral capsid antigen (VCA) of Epstein-Barr virus (EBV) were determined in hospital staff members treating patients with nasopharyngeal carcinoma (NPC). No definite IgA anti-VCA reaction was observed, but IgG anti-VCA titers were substantially increased in some staff members, suggesting greater EBV exposure. The increases were highest for nurses and clinicians and lowest for medical laboratory and clerical personnel. These findings suggest that NPC patients may constitute a source of EBV infection. (15 refs)

78-2877 **Do Viruses Have a Role in Causing Human Cancer?** (Eng) Temin, H. M. (Viral Oncology and Cell Biology at McArdle Lab., Medical Sch. Center for Health Sciences Univ. of Wisconsin, Madison, WI). *Trends Biochem Sci* 3(4): 80-83; 1978.

Although viruses do not have a direct role in the etiology of most human cancers, they may play necessary roles in the etiology of a few cancers. Various roles for viruses include (1) acting as transforming agents, (2) effecting genetic changes that result in cancer, (3) acting as partial or cocarcinogens, or (4) activating preexisting cancer genes or causing genetic variation leading to the formation of cancer genes. It is also possible that genetic variation in cellular processes related to those used primarily in viral replication could cause tumors. The most likely human cancers to have virus involvement are nasopharyngeal carcinoma and Burkitt's lymphoma. In both cases, the Epstein-Barr virus has been found in nearly all the cancers; however, the virus may be present only because the tumor cells provide a good host for virus persistence. Hepatitis or infection by hepatitis B virus appears to be a precursor of liver cancer and products related to or analogous to gene products of retroviruses have been reported in some human leukemias and mammary tumors. It is believed that genetic variation in cellular processes related to those used in virus replication could make cells susceptible to the action of non-viral carcinogens such as cigarette smoke and sunlight. (26 refs)

78-2878 **Hepatitis B Virus and Hepatocellular Carcinoma (Meeting Abstract).** (Eng) Omata, M. (USC-Liver Unit, John Wesley Hosp., Los Angeles, CA); Ashcavai, M.; Liew, C. T.; Peters, R. L. *Gastroenterology* 74(5, part 2): 1169; 1978. (no refs)

78-2879 **Comparative Optical Properties of Free and Assembled Hexon Capsomeres of Human Adenovirus Type 2.** (Eng) Boulanger, P. A. (Unite de Virologie No. 102, INSERM, Place de Verdun, Lille, France); Devaux, C.; Loucheux-Lefebvre, M. H. *Febs Lett* 85(1): 52-56; 1978.

The optical properties of free hexon capsomeres and of interlocking hexons (ninemers) of human adenovirus type 2 were studied to determine the effects of changes in the conformational structure of the protein chain upon capsomere assembly. The circular dichroism spectra at 180-250 nanometers (nm) were identical for both kinds of hexons. Between 250-320 nm, however, differences were noted. A shoulder observed at 302 nm for the ninemers was not found in the hexon monomer spectra. At 290 nm and 283 nm, the dichroic bands were more intense for the hexon ninemers than for the monomers. Furthermore, a dichroic band was visible at 275 nm only in the ninemer spectra. The amino acid composition of the ninemers and free hexon capsomeres was identical, and the bands could be correlated to specific residues involved in hexon assembly. The shoulder at approx 300 nm suggested that tryptophan residues were in a disturbed electronic environment within the ninemers. The band at 290 nm was induced by tryptophan-indole rings. The band at 283 nm was also probably due to tryptophan residues. (27 refs)

78-2880 **Characterization and Sequence Analysis of a Recombination Site in the Hybrid Virus $Ad2+ND_1$.** (Eng) Zain, B. S. (Cold Spring Harbor Lab., Cold Spring Harbor, NY, 11524); Roberts, R. J. *J Mol Biol* 120(1): 13-31; 1978.

Restriction endonuclease mapping of an adenovirus-simian virus 40 (SV40) hybrid virus and adenovirus 2 (Ad2) DNA allowed the characterization of fragments of the nondefective hybrid $Ad2+ND_1$, which contained the two junctions between SV40 sequences and Ad2 sequences. Nucleotide sequence analysis in $Ad2+ND_1$ and the two parent strains allowed identification of the nucleotides involved in recombination. No sequence homology was detected between the parent DNA's. (45 refs)

78-2881 **Groups of Adenovirus Type 2 mRNA's Derived from a Large Primary Transcript: Probable Nuclear Origin and Possible Common 3′ Ends.** (Eng) Nevins, J. R. (Rockefeller Univ., New York, NY, 10021); Darnell, J. E. *J Virol* 25(3): 811-823; 1978.

The number and relative amounts of various messenger RNA (mRNA) molecules derived from a large primary transcript during adenovirus type 2 infection were mapped and studied to determine whether the formation of all the relevant mRNA's is a nuclear event. Hybridization of labeled late mRNA to a series of DNA restriction fragments representing the right-hand 70% of the genome indicated at least 12 discrete mRNA's that appeared to fall into five groups, each possibly containing a common 3′ terminus. The processing necessary to generate these mRNA's apparently occurred in the nucleus. All the mRNA's appeared to contain a sequence of approx 100 nucleotides complementary to a fragment with viral DNA coordinates 25.5-27.9. Furthermore, this fragment contained one of the regions previously found to be spliced onto the 5′ end of late adenovirus type 2 mRNA's. Because the sequences to be spliced existed only once per large transcript, any of the mRNA-specific regions might only have been preserved from a small fraction of the transcripts. Measurement of the transport efficiency of regions of the large nuclear transcript showed that only 15%-25% of any particular region was transported to the cytoplasm. Thus, the large late nuclear transcript can be processed in the nucleus to yield any one of approx 12 mRNA's; the unused portions of the primary transcript then accumulate in the nucleus or are destroyed. (46 refs)

78-2882 **Transcription of Adenovirus RNA in Permissive and Nonpermissive Infections.** (Eng) Farber, M. S. (Dept. Medicine and Cell Biology, Albert Einstein Coll. Medicine, Bronx, NY, 10461); Baum, S. G. *J Virol* 27(1): 136-148; 1978.

The mechanism of blocked replication of human adenoviruses in monkey cells and the way in which simian virus 40 (SV40) coinfection overcomes this block were examined. Previous experiments had placed the block at the level of transcription or translation of adenovirus messenger RNA (mRNA). Thus, the transcription process was investigated in CV-1 monkey cells infected with adenovirus type 2 (Ad2) at 3 plaque-forming units (PFU)/cell (unenhanced infection), in CV-1 cells infected with Ad2 at 10 PFU/cell SV40 (enhanced infection), and in permissive human HeLa cells. Ad2 mRNA from the enhanced monkey cells appeared to be identical to Ad2 mRNA from the HeLa cells. This indicated that SV40 coinfection did not overcome the blocked replication by substituting for a missing Ad2 transcript. Comparison of viral mRNA from enhanced and unenhanced monkey cell infection revealed two types of transcriptional discrepancies. There was a decrease in both the complexity and the relative abundance of several regions of the enhanced adenovirus mRNA. However, neither of these transcriptional defects was sufficient to explain completely the difference in yields of infectious virus and viral protein seen in the two types of infection. (38 refs)

78-2885 **Isolation and Characterization of a Slow-migrating Class of Adenovirus Type 2 Hexons.** (Eng) Boulanger, P. (Unite de Recherches, no. 102 de l'INSERM, 2, Place de Verdun, 59045 Lille Cedex, France); Devaux, C.; Lemay, P. *Virology* 84(2): 456-468; 1978.

The biochemical and immunological properties of two classes of hexons, normal hexons and slow hexons, isolated from KB cells infected with type 2 human adenovirus, were compared. The slow hexons were similar in shape and morphology to normal hexons but differed from them in electric charge. They had a lower electrophoretic mobility, a higher isoelectric point, and a greater type-specific antigenicity than the normal hexons. Polypeptide analysis of the slow hexons revealed that they consisted of a trimeric arrangement of polypeptide subunits of mol wt 115,000; ie, they contained 50 less amino acid residues than the normal hexons (mol wt 120,000). The N-terminal end of their polypeptide subunit was not blocked by acetylation, as in normal hexons, suggesting that proteolytic cleavage occurred at the N terminus. Since such proteolytically processed hexons could not be detected in the adenovirion, it seems likely that these slow hexons represent aberrant hexons occurring variably in some massively infected cell cultures and that they are not involved in adenovirus morphogenesis. (22 refs)

78-2886 **Adenovirus Core Protein Synthesis in the Absence of Viral DNA Synthesis Late in Infection.** (Eng) Kit, G. (Dept. Molecular Biology, Univ. California, Berkeley, CA, 94720); Daniell, E. *J Virol* 27(1): 74-80; 1978.

An attempt was made to determine if adenovirus (Ad) DNA synthesis and core protein synthesis exhibit a tight coupling similar to that observed between cell and/or papovavirus DNA synthesis and histone synthesis. Acid extraction of the Ad type 5 core proteins V, VII, and pVII (precursor to VII) from infected HeLa cells and subsequent electrophoresis of the proteins on a 15% acrylamide-2.5 M urea-0.9 N acetic acid (pH 2.7) gel revealed that the electrophoretic mobilities of peptide VII and histone H1, both of which have a mol wt of about 18,000, are similar. Peptide V had a much slower mobility. The core proteins were coded for by late adenovirus messenger RNA. When DNA synthesis was inhibited before its initiation by the addition of cytosine arabinoside (2, 20, or 200 μg/ml) to the medium or by growing Ad H5 ts125 (a temperature-sensitive mutant for DNA replication) at the nonpermissive temperature (40 C), core proteins were not synthesized. However, when DNA synthesis was inhibited after it had been initiated, core proteins continued to be synthesized. Because core protein synthesis continued > 8 hr after the inhibition of viral DNA synthesis, it appears that the uncoupling of viral DNA synthesis and core protein synthesis was permanent. This result is in contrast to the tight coupling of cell and/or papovavirus DNA synthesis and histone synthesis. In these cases, histone gene expression depends on continual DNA synthesis. (30 refs)

78-2887 **Analysis of the Genome of Type 7 Simian Adenovirus Using Restrictases.** (Eng) Naroditsky, B. S. (D.I. Ivanovsky Inst. Virology, USSR Acad. Medical Sciences, Gamaleya Str., 16, Moscow 123098, USSR); Zavizion, B. A.; Karamov, E. V.; Tikhonenko, T. I. *Nucleic Acids Res* 5(3): 999-1011; 1978.

The physical map of simian adenovirus-7 (SA-7) DNA was compiled using the following restricting endonucleases: R.EcoRI, R.BamI, and R.SalI. Since Sa-7 DNA has only one recognition site for R.EcoRI, cleavage with this enzyme gave rise to two fragments with mol wts of 12.0 and 10.0 x 10^6. Complete cleavage of SA-7 DNA with R. BamI gave rise to seven fragments with mol wts of 6.6, 5.9, 3.8, 2.7, 1.3, 0.7, and 0.6 x 10^6. Simultaneous cleavage of the genome by R.BamI and R.EcoRI showed that the recognition site for R.EcoRI is in R.BamI fragment C. The order of the R.BamI fragments in SA-7 DNA is E-A-D-F-C-G-B. Complete cleavage of SA-7 DNA by R.SalI yielded six fragments with mol wts of 8.1, 5.5, 4.3, 2.45, 1.2, and 0.6 x 10^6. The order of the R.SalI fragments is A-B-D-F-E-C, and the recognition site for R.EcoRI is localized in R.SalI fragment B. It is likely that the middle part of SA-7 DNA, where the recognition sites for R.BamI and R.SalI are localized, is rich in guanosine-cytidine pairs. According to previous studies, it is this part of the genome that is responsible for the oncogenicity of the virus. (15 refs)

78-2888 **Detection of Adenovirus 12-induced DNA-binding Protein in Infected and Transformed Cells with Monkey Antisera.** (Eng) Komatsu, T. (Dept. Enteroviruses, Natl. Inst. Health, Tokyo, Japan); Shiroki, K.; Shimojo, H. *Microbiol Immunol* 21(6): 339-342; 1977.

Antisera to adenovirus 12 (Ad12) DNA-binding protein (DBP) were prepared in the autochthonous monkey system and used to detect Ad12 DBP in Ad12-infected and -transformed cells. In human embryo kidney cells infected with Ad12 and stained with anti-DBP conjugate, fluorescent dots and granules were observed in the nucleus. When cynomolgus monkey kidney (CMK) cells were similarly infected and examined, fluorescent dots and granules were also observed. It is suggested that the fluorescent dots are specific structures related to the replication of Ad12 DNA. Studies with rat cells transformed with wild type or temperature-sensitive (ts) Ad12 indicated that most of the rat cell clones transformed by Ad12 wild-type or tsB contained DBP. None of the rat cells transformed by Ad12tsA contained DBP. Since AD12tsA is defective in the synthesis of DBP at the nonpermissive temperature, it is suggested that the tsA gene is either absent or defective in the synthesis of DBP in tsA-transformed cells. (9 refs)

78-2889 **RNA Associated with Murine Intracisternal Type A Particles Codes for the Main Particle Protein.** (Eng) Paterson, B. M. (Lab. Biochemistry, NCI, Bethesda, MD, 20014); Segal, S.; Lueders, K. K.; Kuff, E. L. *J Virol* 27(1): 118-126; 1978.

Intracisternal A-type particles were isolated from MOPC-104E myelomas grown sc in BALB/c mice and from cultured A/Jax mouse neuroblastoma (N4) cells. Polyadenylated RNA was prepared from the particles and tested in a cell-free translation system derived from rabbit reticulocytes. RNA from the two sources directed the synthesis of multiple polypeptides with similar distributions of electrophoretic mobilities in sodium dodecyl sulfate-polyacrylamide gels, including one component of the same size as the major A-particle structural protein (73,000 daltons). Analysis of the RNA's by electrophoresis in methyl mercury-agarose gels revealed a 35S component common to A particles from both cell types. This was the major component of the N4 preparations, but a 28S species predominated in the case of MOPC-104E. These two RNA's (35S from N4 cells and 28S from MOPC-104E), when isolated on isokinetic sucrose gradients, directed the synthesis of a 73,000-mol wt polypeptide that comigrated on gels with authentic A-particle structural protein. Identity of the cell-free product was confirmed by two-dimensional analysis of the ^{35}S-methionine-labeled tryptic peptides. The N4 RNA preparations also contained a major 32S component that did not code effectively for the A-particle structural protein. (39 refs)

78-2890 **Role of Gross A Virus-Induced Soluble Products as Potential Early Promoters of Thymic Carcinogenesis and Deregulators of Splenic Immune Responses in AKR Mice (Meeting Abstract).** (Eng) Ranney, D. F. (Northwestern Univ., Chicago, IL, 90024); Beardsley, T. R. *Fed Proc* 37(6): 1560; 1978. (no refs)

78-2891 **B-Tropic Oncornavirus Production by BALB/c Methylcholanthrene-induced Sarcoma Cells.** (Eng) Gillespie, G. Y. (Dept. Immunopathology, Scripps Clinic and Res. Foundation, 10666 N. Torrey Pines Rd., La Jolla, CA, 92037); Jensen, F. C.; Russell, S. W. *Int J Cancer* 21(2): 234-238; 1978.

Six oncogenic cell lines (M-133 to M-138) were established from primary sarcomas that developed in male BALB/cSt mice inoculated sc with 1 mg methylcholanthrene 5.5 mo after thymectomy. Injection of 10^5-10^6 cells from these lines induced tumors in all mice tested, and only M-135 failed to induce tumors with an inoculum size of 10^4 cells. Virion-associated reverse transcriptase (RT) activity was detected in supernatants from 4/6 lines, with M-138 supernatant fluid having the highest activity. One of the four RT-positive lines (M-137) produced xenotropic murine leukemia virus (MuLV) exclusively; the other three lines released only ecotropic MuLV, which infected secondary BALB/c mouse embryo fibroblasts but not those from NIH Swiss embryos. B-tropic MuLV from M-138 was used to infect subconfluent monolayers of BALB/c or NIH Swiss mouse embryo fibroblasts. Seven days later, B-tropic MuLV was present in large quantities in the BALB/c culture, but there was no evidence of infection in the NIH culture. Litters of BALB/c and NIH Swiss mice were inoculated ip with 3.6-6.0 x 10^4 plaque-forming units of M-138. All neonatal BALB/c mice demonstrated significant levels of p30 in their circulation, but the plasma from NIH mice remained negative for the antigen. Although the BALB/c mice remained positive for p30 for 9 mo, none of the animals developed clinical signs of leukemia. These findings show that endogenous MuLV may be produced by neoplastic cells induced in vivo with a chemical carcinogen. They underline the danger in assuming that a cell line is virus-free because it was isolated from a chemically-induced tumor. (35 refs)

78-2892 **T1 Oligonucleotides That Segregate with Tropism and with Properties of gp70 in Recombinants Between N- and B-tropic Murine Leukemia Viruses.** (Eng) Faller, D. V. (Dept. Biology, Center Cancer Res., Massachusetts Inst. Technology, Cambridge, MA, 02139); Hopkins, N. *J Virol* 26(1): 153-158; 1978.

The RNase T1-resistant oligonucleotides derived from the genomes of 16 recombinants between N- and B-tropic murine leukemia viruses of BALB/c mice were examined. SP-N, an N-tropic C-type virus that makes small XC plaques, and LP-B, a B-tropic virus that makes large XC plaques, served as parental viruses. These parental viruses also differed with respect to the electrophoretic mobility of virion proteins p15, p30, and gp70; their ability to induce GIX antigen on infected cells; and the presence of 6-8 of 36-38 large T1 oligonucleotides. One SP-N-specific T1 oligonucleotide was inherited by all 16 N-tropic recombinants and, thus, appears to be linked to N-tropism. This oligonucleotide lies in the 5′ third of the oligonucleotide map of SP-N. One LP-B-specific T1 oligonucleotide was inherited by all 11 recombinants whose gp70 had an electrophoretic mobility like that of LP-B gp70 and that, like LP-B, failed to induce GIX. This oligonucleotide lies in the 3′ third of the oligonucleotide map of LP-B. (23 refs)

78-2893 **Incidence in South-west Scotland of Hepatitis B Surface Antigen in the Liver of Patients with Hepatocellular Carcinoma.** (Eng) Turbitt, M. L. (Dept. Pathology, Glasgow Royal Infirmary, Stobhill Hosp., Glasgow, UK); Patrick, R. S.; Goudie, R.B.; Buchanan, W. M. *J Clin Pathol* 30(12): 1124-1128; 1977.

An immunoperoxidase technique for staining hepatitis B surface antigen (HBsAG) was applied to histologic sections of liver tissue stored as paraffin blocks, and a retrospective study was made of the incidence of the antigen in 81 cases of primary hepatocellular carcinoma (PHC) in southwest Scotland. PHC is responsible for only 0.46% of the deaths in this area, and, according to radioimmunoassay, HBs antigenemia is found in only 1/500 of the population. HBsAg was found in 8/81 cases of PHC and 4/82 cases of cirrhosis. There was no positive staining in 112 controls without overt liver disease matched for age and sex. Two mechanisms may occur; infection with hepatitis virus may progress to macronodular cirrhosis, which may later be complicated by PHC, or continuing infection may produce PHC in an otherwise normal liver. An alternative explantion for the findings could be that PHC activates latent hepatitis B virus, with the production of HBsAg in infected cells. This coincides with the observation that 7.5% of the normal people in southwest Scotland have antibody to HBsAg. (7 refs)

78-2894 **Rapid Induction of Colony Stimulating Activity (CSA)-Independent Granulocytic Colonies in Purified Bone Marrow Myeloid Cells by In Vitro Infection with RNA Type-C Viruses (Meeting Abstract).** (Eng) Greenberger, J. S. (Joint Center Radiation Therapy and Sidney Farber Cancer Inst., Boston, MA, 02115); Davisson, P. B.; Gans, P. J. *Proc Am Assoc Cancer Res* 19: 117; 1978. (no refs)

78-2895 **A Primary Target Demonstrating a Biologic Effect of RNA Type-C Leukemia Virus Infection is the Committed Granulocyte-Macrophage Progenitor Cell (Meeting Abstract).** (Eng) Greenberger, J. S. (Joint Center Radiation Therapy, Boston, MA); Davisson, P. B.; Gans, P. J. *Clin Res* 26(3): 347A; 1978. (no refs)

78-2896 **Structural Analysis of the Major Envelope Glycoprotein (gp70) of the Amphotropic and Ecotropic Type C Viruses of Wild Mice.** (Eng) Bryant, M. L. (Dept. Pathology, Univ. of Southern California Sch. Medicine, Los Angeles, CA); Pal, B. K.; Gardner, M. B.; Elder, J. H.; Jensen, F. C.; Lerner, R. A. *Virology* 84(2): 348-358; 1978.

Virus-associated and free serum gp70's major envelope glycoprotein were isolated from wild mice (*Mus musculus*) by immunoaffinity column chromatography and analyzed by two-dimensional tryptic peptide mapping procedures. The structure of the wild mouse gp70's was compared with that of homologous viral and serum gp70's of laboratory mouse strains. The results indicate that the gp70's of wild mouse ecotropic and amphotropic murine leukemia viruses (MuLV) are structurally divergent. The gp70's of wild mouse ecotropic viruses are more similar in structure to the Gross-AKR MuLV subgroup than to the Friend-Moloney-Rauscher subgroup. The gp70's of the amphotropic wild mouse viruses are highly conserved in structure and are closely related to those of one group of xenotropic MuLV found in laboratory mice. Non-virion-associated free serum gp70 of wild mice is homologous to that of inbred laboratory mouse strains and resembles the gp70 of a xenotropic virus spontaneously produced in NZB mice. These findings, combined with other results, suggest that multiple proviral sequences, each encoding a unique gp70 molecule, can be expressed in a give
mouse and that the presence of particular proviral gene se
quences can be identified by primary structural analysis o
specific gp70 molecules. (26 refs)

78-2897 **Biochemical Properties of Endogenous Rat C
type Viruses.** (Eng) Svec, J. (Cancer Res. Inst
Slovak Acad. Sciences, 880 32 Bratislava, Czechoslovakia
Michalides, R. *Neoplasma* 24(6): 601-614; 1977.

Biochemical properties of two endogenous rat le
kemia viruses (Sprague-Dawley, SD-RaLV, an
Wistar, W-RaLV) were examined in in vitro studie
Both SD-RaLV and W-RaLV particles, which we
obtained from spontaneously transformed and/or activ
ly replicating rat embryo fibroblasts, were mo
phologically and biochemically related to know
oncornaviruses. They are of the C-type, have a buo
ant density of 1.15 g/cm^3 in sucrose gradients, and contai
high-mol-wt RNA. The RaLV-associated DNA polymeras
exhibited both exogenous (polynucleotide-templated) and e
dogenous (viral RNA-templated) activity. The enzym
strongly preferred Mn^{2+} over Mg^{2+} ions, with max reactiv
ty occurring at 0.1 mM MnCl. The endogenous nature
SD-RaLV and W-RaLV was confirmed by molecular hybri
ization experiments. The number of proviral sequences w
calculated as 84 per haploid cell genome by competition h
bridization assays. Although it is not clear whether RaL
induced transformation is attributable to direct viral onc
genesis or to derepression or transduction of rat cellular onc
genes, these results demonstrate that the RaLV particles, a
though endogenous, contain the necessary enzymes f
reverse transcription and integration of the viral genome in
the host cell DNA. (38 refs)

78-2898 **Type-C Virus Structural Antigens on the Su
face of the Infected Cell as Determined by
Humoral Cytotoxicity Assay.** (Eng) Kende, M. (Lab. RN
Tumor Viruses, NCI, NIH, Bethesda, MD, 20014); Sass,
Hino, S.; Donahoe, R. M.; Kelloff, G. J. *Int J Cancer* 21(
194-203; 1978.

Antisera produced against the Rauscher murine leukem
virus (R-MuLV) proteins gp70, p12, p30, p10, and p
(E) were characterized by immunoprecipitation
highly purified labeled proteins of R-MuLV and sele
ed proteins of naturally occurring Class I, II, and
endogenous murine C-type viruses. The cytotoxici
of gp70 and p12 antisera showed a predominant ty
specificity to R-MuLV, but these antisera had va
ing degrees of cross-reactivity to the three kno
classes of endogenous C-type viruses. Immunoprec
tation of purified proteins with these antisera produced rea
tivity patterns approximating those obtained with humor

cytotoxicity. Unlike gp70, the cytotoxic reactivity of p12 antisera did not correlate well with the intact virus content or the virus-producing ability of different R-MuLV shedding mouse cells. Cytotoxic activity was not observed with p10 or p30 antisera, and virus-specific cytotoxic activity was not observed with p15 (E). Immunization of three strains of mice differing in their endogenous C-type virus expression with inactivated, disrupted R-MuLV yielded antisera active in radioimmunoassays with gp70, p12, p30, p15, and p10. The relationship of the gp70 and p12 immune response to the antiviral and antitumor effector immune responses operative in vivo is not known. (31 refs)

78-2899 **Use of Cowan I *Staphylococcus aureus* for Radioimmunoassay of Retrovirus Proteins.** (Fre) Deshayes, L. (Laboratoire d'Immunologie et de Virologie des Tumeurs, Hopital Cochin, Bat. G.-Roussy, 27, rue du Faubourg-Saint-Jacques, 75674 Paris Cedex 14, France); Levy, D.; Fournier, G.; Gilly, L. *C R Acad Sci [D] (Paris)* 286(5): 435-438; 1978.

Cowan I strain *Staphylococcus aureus* was used in the radioimmunoassay of C-type virus polypeptides in (1) bovine leukemia virus, (2) Rauscher murine leukemia virus, (3) serum from leukemic cows, (4) serum from a horse immunized against bovine leukemia virus, (5) serum from a rat immunized against a murine sarcoma virus-induced sarcoma, and (6) cow, rat and horse sera with rabbit antibodies. The use of *S. aureus* had several advantages (ease of preparation, speed and completeness of reaction between antigen and antibody) over the antibody immune sera generally used in radioimmunoassays. (11 refs)

78-2900 **Enhancement of the Growth of Implanted Tumors by a Murine Retrovirus (Meeting Abstract).** (Eng) Dennis, A. J. (Battelle's Columbus Lab., Columbus, OH, 43201); Barker, A. D.; Rice, J. M. *Fed Proc* 37(6): 1280; 1978. (no refs)

78-2901 **MAC-1, a New Genetically Transmitted Type C Virus of Primates: "Low Frequency" Activation from Stumptail Monkey Cell Cultures.** (Eng) Todaro, G. J. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD, 20014); Benveniste, R. E.; Sherwin, S. A.; Sherr, C. J. *Cell* 13(4): 775-782; 1978.

A new class of endogenous primate C-type virus was isolated from a continuous tissue culture line of *Macaca arctoides* (stumptail monkey) spleen cells by cocultivation with a human cell line. The virus, designated MAC-1, can be transmitted to human and feline cells in tissue culture. By immunological and nucleic acid hybridization criteria, MAC-1 shows no detectable homology to the baboon C-type viruses, even though viral genes related to the latter group are readily detected in *M. arctoides* cellular DNA. Viral gene sequences related to the MAC-1 genome are present in multiple copies (50-150 per haploid genome) in Old World primates and are expressed in the cellular RNA's of uninfected and ostensibly virus-free primate cells and tissues. There are, therefore, at least two distinct sets of genetically transmitted Old World primate C-type viral genes, each of which is found in multiple copies in normal primate cellular DNA. (26 refs)

78-2902 **Infectivity of Endogenous Baboon Type-C Virus-Related Genes.** (Eng) McAllister, R. M. (Childrens Hosp. Los Angeles, Los Angeles, CA); Nicolson, M. O.; Heberling, R.; Charman, H.; Rice, N.; Gilden, R. V. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 135-138; 1978.

DNA's from two baboon placentas, four embryonic tissues, and three embryonic cell lines were tested for infectivity in human rhabdomyosarcoma TE-32 cells and dog D-17 sarcoma cells. The DNA's of two placentas and one cell line derived from two baboons were infectious. These materials released infectious baboon virus and contained about 100 viral genome equivalents per haploid gene. However, an embryonic cell line from a third baboon was not infectious, although it also contained 100 viral genomes and released virus. DNA's of the four embryonic tissues and one embryonic cell line from a fourth baboon contained only 20 genomes, did not release virus, and were not infectious. TE-32 and D-17 cells infected with baboon virus contained only 5-6 genome equivalents, but they released high virus titers and their DNA's contained infectious baboon provirus. These results demonstrate the complexity of the factors influencing the infectivity of baboon C-type virus-related genes. (11 refs)

78-2903 **Immunological Demonstration of Oncornavirus Genome in Leucocytes in Acute and Chronic Myelogenous Leukaemia and Preleukaemia.** (Eng) Toth, F. D. (Inst. Microbiology and 2nd Dept. Medicine, Univ. Medical Sch., H-4012 Debrecen, Hungary); Jako, J.; Vaczi, L.; Rak, K.; Redai, I. *Acta Microbiol Acad Sci Hung* 24(4): 331-339; 1977.

Anti-LPV p30 serum and antisera to the corresponding antigens of different mammalian C-type oncornaviruses were used to demonstrate C-type oncornavirus cytoplasmic antigens in the peripheral WBC of 10 patients with acute myelogenous leukemia (AML), 9 potentially preleukemic patients, 16 patients with chronic myelogenous leukemia (CML), and 42 control patients with cytopenia or nonhematologic disease. Indirect immunofluorescence testing showed the WBC of all AML patients to be positive with anti-LPV serum and negative with anti-feline leukemia virus serum. These WBC also cross-reacted with antisera to simian and/or murine cytoplasmic oncornavirus antigens, depending on the stage of disease of the patient. Of the 9 potentially preleukemic patients, 6 had LPV-p30-positive WBC, and most of these cross-reacted with antisera to simian p30 antigens. Of 11 CML patients responding to chemotherapy, 5 were negative for oncornavirus cytoplasmic antigens and 6 showed endogenous oncornavirus antigens in the WBC of the remaining five CML patients, including three poor responders in the early and fully developed blastic stages. Cytoplasmic fluorescence with anti-baboon serum was observed in two controls; all the others were negative to all antisera. (25 refs)

78-2904 **Cross-Reactivity of Mammalian C-Type Viruses in Virion Precipitation Reaction.** (Rus) Zakharova, L. G. (D. I. Ivanovsky Inst. Virology, Moscow, USSR); Al'tshtein, A. D.; Zhdanov, V. M. *Vopr Virusol* (1): 25-31; 1978.

Use of the virion precipitation reaction (VPR) to differentiate among the various C-type viruses is described. Incubation of Rauscher leukemia virus, Gross leukemia virus (G-MuLV), murine sarcoma virus (NIH-MSV), feline leukemia virus, endogenous feline virus (RD-114), endogenous baboon virus (BEV), exogenous simian sarcoma virus, exogenous gibbon lymphoma virus, Prague strain of avian Rous sarcoma virus (Pr-RSV), and murine mammary tumor virus (MMTV) with goat immune sera against the test viruses and against bovine leukemia virus (BLV) revealed cross-reacting antigenic determinants on the surface of RD-114, NIH-MuLV, and G-MuLV. These determinants could not be detected on the surface of BLV, Pr-RSV, and MMTV. (18 refs)

78-2905 **C-Type Oncornaviral Antigens in Cocultures of Human Leukaemic Bone Marrow Cells.** (Eng) Zurcher, C. (Inst. Experimental Gerontology TNO, Rijswijk, Netherlands); Coolen, J.; Nooter, K.; Haaijman, J. J.; Koch, G.; Bentvelzen, P. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 144-147; 1978.

In an attempt to increase the expression of C-type virus antigens in human bone tumor cultures, bone marrow (BM) from eight leukemia patients was cocultivated with a dog thymus cell line (A7573) permissive for the propagation of human C-type virus. Three leukemia BM cocultures showed a clear-cut cytoplasmic fluorescence after incubation with antisera against the p30 antigen of the simian sarcoma virus complex (SSV). The three patients with positive reactions were children with acute lymphoblastic leukemia. No fluorescence was found in cocultured BM from eight patients with nonleukemic hematological disorders or from seven normal controls. Reactions with antisera against Rauscher murine leukemia virus were negative. Tests of antisera specificity indicated that the SSV-related information was present in the original BM samples and that cocultivation with A7573 cells resulted in virus antigen expression. (4 refs)

78-2906 **Possible Significance of Type-C Viral Information in Human Leukemic Cells.** (Eng) Campbell, W. F. (Mayo Clinic, Rochester, MN, 55901); Hoagland, H. C.; Smith, D. M. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 150-153; 1978.

Short-term cultures of acute myelogenous leukemia (AML) cells released virus particles containing reverse transcriptase activity and a high-mol-wt RNA (60S) that shared limited homology with woolly monkey sarcoma virus, but not with baboon endogenous virus (BEV) or murine sarcoma virus (MSV). To determine the origin of the C-type virus, a complementary DNA (cDNA) transcript of the viral RNA was prepared using avian myeloblastosis virus reverse transcriptase. Preliminary hybridization studies indicated that DNA from leukemic and nonleukemic cells contained comparable levels of homology with the AML cDNA probe, but that selective expression of the genome occurred only in leukemic cells. The AML viral cDNA hybridized to 50%-100% of leukemic cell RNA, compared with 6%-9% of nonleukemic cell RNA. (15 refs)

78-2907 **Detection of Common Antigenic Determinants in the Capsids of D-Type (Mason-Pfizer) and C-Type Mammalian Viruses by Virion Precipitation Reaction.** (Rus) Al'tshtein, A. D. (D. I. Ivanovskii Inst. Virology, Moscow, USSR); Zakharova, L. G.; Zhdanov, V M. *Vopr Virusol* (3): 309-314; 1978.

The virion precipitation assay was used to analyze and compare the capsid antigens of D-type Mason-Pfizer monkey virus (M-PMV) and a series of B- and C-type oncornaviruses. Goat immune sera against M-PMV precipitated the mammalian C-type viruses Rauscher murine leukemia virus

(MuLV), Gross MuLV, NIH MuLV, feline leukemia virus, RD-114, baboon endogenous virus, simian sarcoma virus 1, and gibbon ape leukemia virus, but not mouse mammary tumor virus, Prague strain Rous sarcoma virus, and bovine leukemia virus. (13 refs)

78-2908 **Skunks Have Gene Sequences in Their Cellular DNA Related to Squirrel Monkey Retrovirus: Transmission Between Species of a New World Primate Endogenous Type D Retrovirus.** (Eng) Benveniste, R. E. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD, 20014); Wilson, G. L.; Todaro, G. J. *Biochem Biophys Res Commun* 81(4): 1363-1369; 1978.

The possibility that genetically transmitted viruses of New World primates could have been transmitted to the DNA of other families of mammals was tested using an endogenous D-type virus from squirrel monkeys. In a series of molecular hybridization experiments with the DNA's of a variety of primate and nonprimate species, sequences related to the squirrel monkey virus were not detected in any other primate species, including six other genera of New World monkeys. However, when the DNA's of the New World carnivors were examined, the sequences were detected in the cellular DNA of normal tissues of two members of the family Mustelidae, the skunks *Mephitis mephitis* and *Spilogale putorius*. Skunk cellular DNA did not hybridize significantly to a transcript prepared from the other endogenous New World primate virus (owl monkey), to any other primate virus (langur, baboon, stumptail, gibbon), or to cat or mouse retroviruses. It is concluded that the D-type virus was transmitted between the germ lines of the two evolutionarily distant species. This example of interspecies transmission is the first that has been described among New World species and also the first that has been demonstrated for retroviruses other than C-type viruses. 78-2909 **In Vitro Induction of Tumour-specific Immunity. V. Detection of Common Antigenic Determinants of Murine Fibrosarcomas.** (Eng) Burton, R. C. (Genetics Unit, Walter and Eliza Hall Inst. Medical Res., Melbourne, Australia); Warner, N. L. *Br J Cancer* 37(2): 159-170; 1978.

In vivo and in vitro tumor-immune responses of male BALB/c mice to two 3-methylcholanthrene-induced fibrosarcomas (WEHI-164 and -167) and one spontaneous fibrosarcoma (WEHI-11) were examined. When BALB/c mice were immunized to these fibrosarcomas by surgical tumor removal, cross-reacting tumor-associated transplantation antigens (TATA) were detected on all three tumors. Cytotoxic effector cells (CL) were then induced in vitro by coculture of BALB/c spleen cells with the spontaneous or one of the carcinogen-induced fibrosarcomas. These CL were shown to be cytotoxic T cells (Tc) and to be directed against cross-reacting tumor-associated antigens (TAA) on all three tumors by two ^{51}Cr-release assays. The TAA involved in the in vitro induction of Tc were not present on normal adult or fetal tissues. A secondary cytotoxic response was also detected in vitro when spleen cells from mice immunized to a carcinogen-induced fibrosarcoma were tested. The patterns of cross-reactivity detected by the in vivo and primary in vitro tumor-immune responses suggested that the in vivo TATA were not identical to the TAA detected in vitro. (43 refs)

78-2910 **Soluble Suppressor Factor from the Spleens of Tumor-bearing Mice.** (Eng) Subramanian, C. (Dept. Surgery, Univ. Minnesota, P.O. Box 85, Mayo Memorial Building, Minneapolis, MN, 55455); Yu, S.; McKhann, C. F. *Cancer Res* 38(7): 1996-2002; 1978.

A soluble suppressor factor released from the spleens of C3H/HeJ female mice bearing 3-methylcholanthrene-induced tumors (MC43 fibrosarcoma) is described. This factor was released in vitro into the media 3-5 days after culture of spleen cells from tumor-bearing animals, and it suppressed the stimulation of lymph node and spleen cells by tumor antigen or mitogens. Spleens from mice carrying the MC43 tumor for 14 days were capable of producing suppressor factor in vitro, but those from mice bearing the tumor for $\leq$10 days failed to do so. Lymph node cells from the same animals did not produce suppressor factor in vitro. The suppressor factor was produced by a nonadherent cell population, was heat-stable, was lost on dialysis, and did not appear to be tumor antigen or thymidine. (21 refs)

78-2911 **Perturbation of General and Anti-tumor Immune Competence in Mice Bearing a Chemically Induced Tumor (Meeting Abstract).** (Eng) Dean, J. H. (Litton Bionetics, Inc., Kensington, MD, 20795); McCoy, J. L.; Lewis, D. D.; Law, L. W. *Proc Am Assoc Cancer Res* 19: 208; 1978. (no refs)

78-2912 **Stimulation of Malignant Skin Cells by Antibody to Normal Skin Cells of Mice.** (Eng) Heidrick, M. L. (Dept. Biochemistry, Univ. Nebraska Coll. Medicine, 42nd St. and Dewey Ave., Omaha, NB, 68105); Ryan, W. L.; Curtis, G. L. *J Natl Cancer Inst* 60(6): 1419-1425; 1978.

The ability of antibodies developed against normal skin cells to stimulate skin cells transformed by 7,12-dimethylbenz(a)anthracene (DMBA) was determined. Primary cultures of normal skin, containing both fibroblasts and epithelial cells, were obtained from adult A/J mice. Malignant skin cells were obtained by treating a subculture of normal cells with medium containing 0.5 μg/ml DMBA. Transformation was demonstrated by increased growth rate, growth in soft agar, and production of tumors in A/J mice. Antisera developed against the normal cells were cytotoxic to both normal and malignant cells in the presence of complement at a 1:320 dilution. However, dilutions of 1:500 to 1:1,000 in the absence of complement produced growth enhancement of the malignant but not the normal cells. The growth-enhancing properties were present in the γ-globulin fraction of the antisera that contained IgG, IgM, and IgA antibodies. Immunofluorescence studies indicated that antibodies from the sera bound to membranes of both normal and malignant cells. These findings suggest that autoantibodies against normal tissues, which develop as a result of injury or other mechanisms, can specifically stimulate the growth of malignant or premalignant cells. (27 refs)

78-2913 ***Corynebacterium parvum*-Induced Resistance to a Methylcholanthrene Fibrosarcoma.** (Eng) Gupta, J. D. (Children's Medical Res. Foundation, Camperdown, New South Wales 2050, Australia); Morahan, P. S.; Kaplan, A. M. *J Reticuloendothel Soc* 23(1): 1-9; 1978.

The effectiveness of intratumor injections of *Corynebacterium parvum* against the 3-methylcholanthrene-induced tumor

MCA 2182 was determined in male C57BL/6 mice. Injection of 0.5-70 mg/kg *C. parvum* 3 days after tumor transplantation into the footpads produced 50%-88% tumor-free survivors; a dose of 0.056 mg/kg was ineffective. Treated animals with progressing tumors generally showed a survival time similar to that of control animals. Animals surviving without evidence of tumors after treatment with 70 mg/kg demonstrated specific tumor immunity when challenged with the same tumor, but not with a heterologous tumor. Prophylactic footpad inoculation with *C. parvum* 7 or 3 days before tumor inoculation produced more tumor-free survivors than did therapeutic treatment, but the surviving animals did not exhibit specific transplantation resistance. When tumors were treated on day 7 after tumor cell injection, only a dose of 70 mg/kg produced tumor-free survivors. Intratumor injection of *C. parvum*-activated macrophages on day 3, at a ratio of 25 macrophages to each tumor cell previously injected, produced a marked inhibition of tumor growth. Furthermore, a significant number of tumor-free survivors (50%) was observed with intratumor injection of activated macrophages compared to normal macrophages (10%). This effect was not observed with injection on day 7; in fact, a slight tumor growth enhancement was sometimes observed. (22 refs)

78-2914 **Vulnerability of Methylcholanthrene-induced Tumours to Immunity Aroused by Syngeneic Foetal Cells.** (Eng) Medawar, P. B. (Clinical Res. Centre, Watford Road, Harrow, Middlesex, England); Hunt, R. *Nature* 271(5641): 164-165; 1978.

Evidence is presented that protection against tumors is secured by immunity to embryo-specific antigens aroused by normal pregnancy or by deliberate inoculation of embryonic cells. Irradiated CBA fetal cells were injected into CBA mice 7 or 14 days before or after or at the same time as an injection of 50 μg methylcholanthrene (MC). Comparisons among the five groups indicated that injection of embryonic cells 7 or 14 days post-MC promoted tumor growth, but that injection of fetal cells 7 or 14 days pre-MC retarded the onset and lessened the number of induced tumors. These results might explain the influence of parity and age at first childbearing on susceptibility to mammary cancer in humans. The protective effect of an early pregnancy is simulated by the results of experiments in which immunity is aroused before the application of the oncogenic stimulus. The lessened effectiveness or even increased hazard of breast cancer associated with late pregnancy is simulated by the enhancing effect on tumor growth found when the inoculation is deferred until after the application of the oncogenic stimulus. The underlying assumption in both situations is that the transformation from normal to malignant growth occurs very shortly after MC injection and very early in reproductive life. (8 refs.)

78-2915 **Antigenic Differences Between AKR Lymphoma and Thymus Cells Leading to the Detection of a Tumor Antigen Associated with Immunological Enhancement.** (Eng) Laguens, R. P. (Catedra de Patologia II, Facultad de Medicina, Universidad Nacional de La Plata, Buenos Aires, Argentina); Colmerauer, M. E.; Segal, A.; Pasqualini, C. D. *Int J Cancer* 21(6): 779-783; 1978.

An indirect immunofluorescence (IF) test using lymphoma and thymus cells as targets was used to compare the sera of tumor (AKR lymphoma L15)-bearing BALB/c mice progressors with those of mice that had rejected the tumor (regressor). An intensively positive IF reaction was obtained when L15 lymphocyte and thymus cells, either unfixed or acetone-fixed, were incubated with progressor serum. After incubation with regressor serum, however, a positive IF reaction was observed only on unfixed L15 and fixed and unfixed thymus cells. The IF results indicated that the progressor serum contained three different antibodies, designated a, b, and c, that combined with the corresponding antigens, A, B, and C, present on L15 cells. The regressor serum, however, possessed only two of these antibodies, b and c, which reacted with the two antigens (B and C) that L15 shares with thymus cells. In vivo experiments showed that pretreatment of BALB/c mice with the acetone-resistant tumor antigen A of L15 cells led to a significant increase in allogeneic tumor incidence (76%, compared with 37% in controls). It is concluded that in this allogeneic model, an acetone-resistant tumor-specific antigen and its corresponding antibody are involved in tumor enhancement. (18 refs)

78-2916 **H-2 Antigens on a Murine Lymphoma Are Associated with Additional Proteins.** (Eng) Callahan, G. N. (Dept. Immunology, Scripps Clinic and Res. Foundation, 10666 N. Torrey Pines Road, La Jolla, CA 92037); Allison, J. P. *Nature* 271(5641): 165-167; 1978.

Immunochemical evidence is presented for the alteration of histocompatibility (H-2) antigens on tumor cells by association with additional proteins. Normal C3H splenocytes and 6C3HED tumor cells (an estrogen-induced lymphoma) were radiolabeled, extracted with detergent, and reacted with either anti-H2.23 (H-2.23 is the private *K*-locus antigen of the H-2K haplotype) or normal mouse serum. The resulting antigen-antibody complexes were analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. Proteins with mol wts of 45,000 and 12,000, characteristic of detergent-solubilized H-2 and β_2-microglobulins (β_2-μ), were present in the extracts from both normal and tumor cells. Additional major peaks corresponding to mol wts of 70,000 and 55,000 were evident in the 6C3HED cell extract. Similar peaks were obtained when anti-H-2.23 and anti-β_2-μ were reacted with detergent eluates of tumor cells that had been radioiodinated with lactoperoxidase, indicating that the antigens detected were on the cell surface. One possible explanation for these results is that a complex composed of at least one β_2-μ, one H-2 heavy chain, and one or two higher mol wt proteins is formed on the tumor cells. In detergent extracts, this complex precipitates with anti-H-2.23 and anti-β_2-μ as a single entity and then is reduced to its individual protein components when the precipitates are prepared for electrophoresis. (16 refs.)

78-2917 **Resistance to Transplantation of Spontaneous AKR Lymphoma Cells by Substrains of AKR Mice. In Vivo Resistance and Generation of an H-2 Restricted CML Response.** (Eng) Zatz, M. M. (Immunology Branch, NCI, NIH, Bethesda, MD, 20014). *Cell Immunol* 36(2): 251-262; 1978.

The observation that the AKR/J (H-2k, Thy 1.1) and AKR/Cu (H-2k, Thy 1.2) substrains of AKR mice each have a high incidence of T-cell lymphoma between 6 and 12 mo of age, but they reject the spontaneously arising lymphoma of the reciprocal strain, was investigated. During the rejection, splenic precursor cells were generated that, upon secondary stimulation in vitro, resulted in specific cytotoxic T cells. The antigenic component of AKR cells resulting in this secondary cell-mediated lympholysis response resided on both lymphoma and normal T and B cells, and it was distinct from the Thy antigen. Primed AKR/J lymphocytes responded to and lysed only immunogens and targets homologous at the K and/or D end of the major histocompatibility complex (MHC), but primed AKR/Cu cells required homology at the D end of the MHC. (18 refs)

78-2918 **SIM and SIM-R Mice Are Histoincompatible.** (Eng) Furmanski, P. (Dept. Biology, Michigan Cancer Foundation, Detroit, MI, 48201); Dietz, M.; Hines, D. L.; Marcelletti, J. *Virology* 86(1): 287-290; 1978.

Attempts were made to breed SIM and SIM-R mice for congenicity at the Fv-1 locus. SIM mice were permissive for N- and NB-tropic viruses and restricted B-tropic viruses, but the SIM-R mice were permissive for B- and NB-tropic viruses and restricted N-tropic viruses. Histocompatibility was determined by skin graft reactions of the SIM and SIM-R mice. These mice rejected all skin grafts made between them within 14 days of grafting. Further analysis of histocompatibility differences was made in cytotoxicity tests using H-2 typing alloantisera. The results indicated that all antigenic specificities recognized by D-13 serum on SIM-R cells were also present on BALB/c cells, but that the converse was not true. Furthermore, there were differences between SIM and SIM-R cells other than those detected by the D-13 serum. Studies of these differences indicated that although there was a strong reaction in cultures of SIM or SIM-R cells with allogeneic BALB/c or C57BL/6 lymphocytes, there was no significant reaction in mixtures of SIM and SIM-R cells. Thus, although the SIM and SIM-R mice differ in antigens specified by the D end of the major histocompatibility complex (at least as determined by the D-13 serum), they are the same at the closely linked I locus. (23 refs)

78-2919 **Splenomegaly, Anemia and Reticular Neoplasms in the Congenic Resistant Mouse Strain B10.Y.** (Eng) Dux, A. (Dept. Genetics, Netherlands Cancer Inst., Amsterdam, Netherlands); Faraldo, M. J. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 74-77; 1978.

The incidence of spontaneous malignancies was compared in two congenic C57BL mouse strains (B10 and B10.Y) that differ with respect to the major histocompatibility complex (H-2) haplotype. Splenomegaly, which persisted for life, was present in 3-mo-old B10.Y mice (H-2pa). Beginning at age 4 mo, the animals developed severe anemia. Lymphoproliferative lesions appeared by age 4 wk and reticulum cell sarcomas (mostly type B) by age 17 wk. A few type A reticular tumors, lymphocytic leukemias, and plasma cell tumors were also observed. The B10 mice (H-2b) did not develop splenomegaly or anemia, and reticular neoplasms in this strain appeared very late in life. The changes in the B10.Y strain are attributed to the effect of the H-2 complex. (5 refs)

78-2920 **Mammary Leukaemia (ML) Antigen Isolated from L 1210 Leukaemia Cells.** (Eng) Zak-Nejmark, T. (Dept. Tumour Immunology, Ludwik Hirszfeld Inst. Immunology and Experimental Therapy, Wroclaw, Poland); Steuden, J.; Radzikowski, C. *Int J Cancer* 21(4): 490-495; 1978.

Crude 3 M KCl extracts of murine leukemia L-1210 cells purified by polyacrylamide gel electrophoresis (PAGE) and the mammary leukemia (ML) isolated from these cells purified by affinity chromatography were characterized, and their identity was verified by anti-ML sera obtained from allogenic and xenogeneic hosts. The crude, soluble extract from L-1210 cells neutralized the cytotoxic activity from anti-ML and anti-H-2d antisera. The cytotoxic activity of anti-H-2d aloserum (diluted 1:8) was decreased from 100% to 17%. After absorption, the hetero- and alloanti-ML sera also appeared to be noncytotoxic for ML-positive leukemia cells. Selected purified ML-positive fractions and purified ML antigen were analyzed by PAGE. In each instance a single, sharp band was obtained with a mol wt estimated to be 73,500 daltons. Weak bands with mol wt of 80,000 to 90,000 were also observed. The 73,500-dalton band contained carbohydrate. It was estimated that ML antigen constitutes 0.044% of the total cellular proteins and that a single L-1210 cell contains 7.62 x 10^5 molecules of ML antigen. (30 refs)

78-2921 **Viral Structural Antigens on the Surface of Mouse Mammary Tumor Cells Detected by**

Serum Cytotoxicity, Membrane Immunofluorescence and Lactoperoxidase-Catalyzed Iodination (Meeting Abstract). (Eng) Massey, R. J. (Frederick Cancer Res. Center, Frederick, MD); Arthur, L. O.; Fine, D. L.; Schochetman, G. *Fed Proc* 37(6): 1772; 1978. (no refs)

78-2922 **Immunization of Mice Against Murine Mammary Tumor Virus Infection and Mammary Tumor Development.** (Eng) Sarkar, N. H. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Moore, D. H. *Cancer Res* 38(5): 1468-1472; 1978.

Formalin-inactivated whole murine mammary tumor virus (MuMTV), MuMTV membranes, the acid-soluble component of MuMTV, and purified MuMTV glycoprotein with a mol wt of 55,000 (gp55; also called gp52) were used as vaccines in an attempt to identify the MuMTV antigen(s) that can protect C57BL mice from exogenous MuMTV infection and subsequent tumor development. Formalin-inactivated whole MuMTV, MuMTV membranes, and purified MuMTV gp55 were effective immunogens, but the acid-soluble component of MuMTV (containing mainly MuMTV gp55) failed to protect mice from challenge with live virus. These results suggest that MuMTV gp55 is the major immunizing antigen and that its native conformation must be maintained for it to be an effective vaccine. Thus, MuMTV vaccines can control exogenous infection in animals that do not normally overtly express endogenous virus; they can also prevent tumor development in strains of mice that have a low virus load. (26 refs)

78-2923 **Stimulation of Immune Response in Hybrid Mice Following Rauscher Virus Infection.** (Eng) Okunewick, J. P. (Viral Oncology Section, Cancer Res. Unit, Clinical Radiation Therapy Res. Center, Allegheny General Hosp., Pittsburgh, PA, 15212); Meredith, R. F.; Brozovich, B.; Weaver, E. V. *Proc Soc Exp Biol Med* 157(3): 449-452; 1978.

The plaque-forming cell (PFC) response following infection by the NB-tropic strain of Rauscher leukemia virus (RLV) was investigated in the sensitive SJL/J mouse, the resistant C57BL/10 mouse, and their resistant (SJL/J x C57BL/10)F_1 hybrid. With SJL/J mice, a brief elevation in PFC response was observed when the virus was injected 1 day before or immediately before sheep RBC administration. This was followed by a depression in response, reaching minimum levels at day 21. C57BL/10 mice showed a slight depression in PFC response at day 2 followed by an increase that became significant at day 12. With the hybrid, a significant immunodepression was evident at day 1. This was followed by a rapid recovery in PFC response, peaking at a level twice normal by day 8; the level subsequently dropped off but remained high throughout the observation period. C57BL/10 mice showed no increase in spleen size following infection, and although the hybrid showed a threefold increase in spleen size, this did not correspond with the peak of PFC activity. However, some of the increases in PFC response were due to an overall elevated number of spleen cells in the infected hybrid. In contrast, SJL/J mice developed the greatest splenomegaly, but this strain showed virtually complete suppression of the total splenic PFC response. (25 refs)

78-2924 **Contrasting Immune Response Following Rauscher Leukemia Virus Infection in Virus-Susceptible vs. Virus-resistant Mice.** (Eng) Meredith, R. F. (Viral Oncology Section, Cancer Res. Unit, Clinical Radiation Therapy Res. Center, Div. Radiation Oncology, Allegheny General Hosp., Pittsburgh, PA, 15212); Okunewick, J. P.; Brozovich, B. J.; Weaver, E. V. *Dev Comp Immunol* 2(1): 133-146; 1978.

Humoral (plaque-forming) and cellular (mitogenic) immune responses were studied in virus-susceptible SJL/J mice and virus-resistant C57BL/10 mice following their infection with a threshold lethal dose of Rauscher leukemia virus. The plaque-forming response was suppressed in the SJL/J mice, but in the C57BL/10 mice, it was slightly elevated during the second and third weeks after infection. This suppression and elevation correlated with the development of severe viremia and a continued low level titer of virus, respectively. SJL/J mice exhibited splenomegaly with the virus infection, but C57BL/10 mice did not. Increasing the virus dose by a factor of 40 did not significantly alter the humoral response pattern of either strain, and it did not cause the C57BL/10 response to mimic that of the SJL/J mice. For both strains, the cellular and humoral immune response patterns differed. Depression of T-cell-mitogen responses occurred in the SJL/J mice, but at a later time than humoral response suppression. Neither T- nor B cell mitogen responses were affected in the C57BL/10 mice. The effect on mitogen responsiveness appeared to be independent of that on plaque formation in both strains. (40 refs)

78-2925 **T- and B-Cell Populations and Virus Antigen Expression in Lymphoid Tissues of Mice During Moloney- and Gross-Virus Leukemogenesis.** (Eng) Krueger, G. R. (Immunopathology Labs., Pathology Inst., Univ. Cologne, Clinical Center Lindenburg, 5000 Cologne 41, W. Germany); Bedoya, V. A.; Fischer, K. M.; Flesch, H. G. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 316-317; 1978.

The behavior of T and B cells in the lymphoid tissues of mice infected with leukemogenic viruses was studied and correlated with the appearance of virus-related antigens in lymphoid cells. Significant decreases in T- and B-cell receptors were noted before malignant proliferation could be diagnosed histologically. The expression of virus-related antigens was not quantitatively related to the expression of T- and B-cell receptors. Malignant lymphomas did not originate at the site where most cells carrying virus-related antigens were found initially. (6 refs)

78-2926 **Activation of Thymus-dependent Cell-mediated Cytotoxicity Against Virus Induced Tumor Cells by Antibody.** (Eng) Lamon, E. W. (Dept. Surgery, Sch. Medicine, Univ. Alabama in Birmingham, Birmingham, AL, 35294); Whitten, H. D.; Walia, A. S.; Fuson, E. W.; Cox, B. A.; Ayers, R. D. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 462-465; 1978.

The role of antibodies in the induction of antibody-dependent cell-mediated cytotoxicity (ADCC) was investigated. Serum from Moloney murine sarcoma virus (M-MuSV) regressor mice induced cytotoxicity specific for MuSV-transformed cells but not for polyoma virus-transformed cells. Serum from polyoma-immune mice induced thymocyte cytotoxicity only against polyoma-transformed cells and not against MuSV- or simian virus 40 (SV40)-transformed cells. However, antiserum raised against syngeneic embryo fibroblasts induced thymocyte cytotoxicity against all three cell lines. Further studies indicated that the effector cells included thymocytes, with cortisone-resistant medullary thymocytes being the most active. Both IgM and IgG induced ADCC, but the former was 400-500 times more efficient than the latter. The structural bases for IgG and IgM ADCC by T cells appear to be the Fc receptors on the T cells. A soluble IgG Fc receptor released from activated T cells was isolated and found to be a glycoprotein with a mol wt of 40,000 daltons. This protein increased the ability of T cells or macrophages to bind and lyse IgG-sensitized target cells. (12 refs)

78-2927 **Antibody Directed Against Endogenous C-Type Virus Is Immunosuppressive.** (Eng) Moroni, C. (Friedrich Miescher-Institut, P.O. Box 273, CH-4002 Basel, Switzerland); Schumann, G. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 174-175; 1978.

Antiserum against lipopolysaccharide-induced BALB/c endogenous xenotropic C-type virus suppressed the normal immune response of mice to sheep RBC. The immunosuppressive activity of the antiserum was reduced by absorption with xenotropic BALB/c virus and Friend leukemia virus, but not by absorption with Rous sarcoma virus or tobacco mosaic virus. The association between an endogenous viral antigen and immunosuppression is consistent with the hypothesis that endogenous C-type viruses play a role in the immune system. (2 refs)

78-2928 **Binding of Human Antibodies to Purified Primate C-Type Viral Antigens.** (Eng) Kurth, R. (Friedrich Miescher Laboratorium, Max Planck-Gesellschaft, Spemannstrasse 37-39, 74 Tubingen, W. Germany); Teich, N. M.; Weiss, R. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 41-45; 1978.

Human sera from (A) healthy blood donors and (B) laboratory personnel working with C-type animal viruses were examined for the presence of antigens to the simian sarcoma virus/simian sarcoma-associated virus [SSV(SSAV)] complex. Group B tended to have higher antibody titers to SSV(SSAV) than Group A, but wide variations were also apparent within Group B. Although the possibility that these antibodies were induced by nonviral antigens cannot be excluded, it is also possible that oncoviruses of monkeys share antigenic determinants with putative human oncoviruses. 78-2929 **Immune Reactivity of Visna Virus-inoculated Mice.** (Eng) Svennerholm, B. (Dept. Virology, Inst. Medical Microbiology, Univ. Goteborg, Goteborg, Sweden); Strannegard, O.; Lycke, E. *Infect Immun* 20(2): 412-417; 1978.

The effect of Visna virus on the development of humoral and cell-mediated immunity was investigated in Swiss albino mice. Mice were inoculated with crude or purified Visna virus and, 5 days later, immunized with sheep RBC; after another 5 days, direct and indirect plaque-forming cells (PFC) were assayed. A pronounced suppression of direct and indirect PFC was observed. The suppressive effect increased with decreasing concentrations of virus injected; max suppression occurred at a virus dilution of 10^{-4}. The effect of the virus on the secondary antibody response was measured by challenge with sheep RBC 28 days after the initial inoculation. Five days later, the direct PFC response, but not the indirect response was significantly suppressed. Injection of virus 4 or more days before sheep RBC injection inhibited the PFC response. This inhibition was most pronounced if 15 days had elapsed between the virus and sheep RBC injections, but it disappeared if 30 days had elapsed. If the virus was administered after the sheep RBC, enhancement was observed. Heating the virus at 56 C for 30 min abolished its immunosuppressive capacity. Further studies indicated that the number of "background" antibody-producing spleen cells increased slightly after virus injections. Virus was injected into DBA/1J mice before they were sensitized to picryl chloride (PC), and the animals were challenged with PC 5 days after sensitization. A suppressive effect was observed when virus was injected 2 wk before sensitization but not 3 or 4 wk before sensitization. In other experiments with DBA/1J mice, virus diluted 10^{-1} suppressed mitogen-induced DNA synthesis in thymus cell cultures significantly; virus diluted 10^{-3} enhanced the synthesis. No interferon activity could be demonstrated in the Visna virus inocula or in the sera of mice 0-14 days after virus inoculation. (19 refs)

78-2930 **The Detection of a Tumor-Specific Transplantation Antigen on Nonvirus-Producer Cells by Cell-Mediated Cytotoxicity.** (Eng) Smith, K. A. (Hematology Res., Dartmouth Medical Sch., Hanover, NH, 03755); Ferm, M. M.; Gillis, S.; Gillis, A. E. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 355-356; 1977.

Secondary and tertiary in vitro lymphocyte sensitization through mixed tumor-lymphocyte culture led to the successive enhancement of the generation of tumor-specific cytotoxic T lymphocytes, which has allowed the detection of a tumor-specific transplantation antigen on both virus-producing and nonproducer tumor cells. 78-2931 **Cell-mediated Immunity to Antigens Associated with Primate C-Type Oncornaviruses in Pregnant Women.** (Eng) Hirsch, M. S. (Massachusetts Gen. Hosp. and Harvard Med. Sch., Boston, MA); Kelly, A. P.; Kurth, R.; Chapin, D. S.; Fuller, T.; Black, P. H. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 103-105; 1978.

Cell-mediated and humoral immune responses against antigens associated with primate C-type oncornaviruses were evaluated in humans by microcytotoxicity and radioimmunoprecipitation assays. Five of six women tested sequentially during pregnancy developed selective cell-mediated and humoral reactivity against baboon endogenous virus antigens. The responses peaked during the second and third trimesters. No reactivity was observed in any of 10 healthy, nonpregnant subjects (4 women and 6 men). Immune responses against cells infected with the simian sarcoma virus-simian sarcoma-associated virus complex were observed repeatedly in 3/14 nonpregnant and 1/6 pregnant individuals. (15 refs)

78-2932 **Cell-mediated and Humoral Responses to Simian Oncornaviruses Antigens in Humans with Graft.** (Eng) Thiry, L. (Institut Pasteur du Brabant, Brussels, Belgium); Sprecher-Goldberger, S.; Vereerstraeten, P.; Bossens, M.; Neuray, F. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 106-110; 1978.

Cell-mediated responses to simian oncornavirus antigens were studied in 69 pregnant and 49 nonpregnant women. Specific lymphocyte stimulation by Mason-Pfizer (M-P) virus or baboon C-type virus antigens was found in 25%-65% of the pregnant women, the frequency being highest in those with a history of 5-10 pregnancies. Only 5%-13% of the nonpregnant women had lymphocytes responding to one of these two viruses, and only 2%-4% in either group had lymphocytes responding to simian sarcoma virus. From 27% to 30% of the women had antibodies to M-P virus, and the frequency did not alter with pregnancy. Among patients with chronic glomerulonephritis, 8/14 had M-P virus antibodies before kidney transplantation and 16/19 had antibodies posttransplantation. Repeated blood transfusions or some other event related to grafting may be the source of M-P virus antigenic stimulation. (4 refs)

78-2933 **Epstein-Barr Virus-Immune Complexes in Postmortem Kidneys from African Patients with Burkitt's Lymphoma and American Patients With and Without Lymphoma.** (Eng) Sutherland, J. C. (Dept. Pathology, Univ. Maryland, 22 S. Greene St., Baltimore, MD, 21201); Olweny, C. L.; Levine, P. H.; Mardiney, M. R. *J Natl Cancer Inst* 60(5): 941-946; 1978.

Postmortem kidneys from 14 African patients with lymphoma were examined by immunofluorescence (IF) for immunoglobulin (Ig), C3, and, along with 59 kidneys from American patients, for Epstein-Barr virus (EBV)-specific antigen (Ag). Of the American patients, 21 had leukemia, 11 lymphoma, 14 solid tumors, and 13 non-tumor-related illnesses. Both Ig and C3 were detected in a nonlinear pattern in the glomeruli of two kidneys from African patients, one from a patient with Burkitt's lymphoma (BL) and one from a patient with Hodgkin's disease (HD). Ig alone was detected in the glomeruli of three kidneys from BL patients, but two kidneys from BL patients and one from a patient with reticulum cell sarcoma were negative for both Ig and C3. Six kidneys from BL patients could not be evaluated by IF for Ig and C3. EBV-specific Ag was detected in one kidney from a BL patient and in one kidney from an HD patient, both Africans; this Ag was not detected in any of the other African kidneys or in any of the American kidneys. The kidneys from 8 African patients (7 with BL and 1 with HD) and 11 American patients (7 with tumors and 4 without) were homogenized. Viral capsid antigen (VCA) and early antigen antibodies (Ab) were detected in the acid eluates of 4 African kidneys, and VCA Ab alone was detected in 6 American kidneys (3 with tumors and 3 without); none of these kidneys had demonstrable EBV Ag on their glomerular basement membrane (GBM). These findings, which provide evidence for the deposition of EBV Ag-Ab complexes on the GBM of two African kidneys (1 BL and 1 HD), indicated that EBV-related immune complexes may be important in diseases other than BL. (19 refs)

78-2934 **An Immunological Basis for Inhibition of Transformation of Human Lymphocytes by EB Virus.** (Eng) Moss, D. J. (Queensland Inst. Medical Res., Brisbane, Australia); Scott, W.; Pope, J. H. *Nature* 268(5622): 735-736; 1977.

The inhibition of Epstein-Barr virus (EBV)-induced transformation of human lymphocytes was investigated. Inhibition was noted when EBV-infected lymphocytes of three donors with antibody to EBV were cocultivated with fibroblasts from the skin of two adult donors, but not when they were cocultivated with fibroblasts from four fetuses. Inhibition of transformation was not demonstrated with lymphocytes from a donor with antibody to EBV. Nonadherent mononuclear cell populations from 14 donors (10 men, 4 women, aged 5-46 yr) were infected with 0.1 TD50 of QIMR-WIL strain EBV. Nonadherent lymphocytes, with or without antibody to EBV, were uniformly transformed when cultivated alone or with fetal fibroblasts. With adult fibroblasts, however, transformation occurred with lymphocytes from the eight donors without EBV antibody but with none of the five lymphocytes from the six donors with antibody to EBV. Transformation was not dependent on virus dose or cell concentration. Further studies showed that inhibition was dependent on previous EBV infection of the lymphocyte donor, but not of the donor of the adult fibroblast donor. It is concluded that an immunological system capable of inhibiting lymphocyte transformation by EBV is inherent in the mononuclear cells from persons with previous EBV infection. (14 refs)

78-2935 **Factors Affecting Serum IgA Antibody to Epstein-Barr Viral Capsid Antigens in Nasopharyngeal Carcinoma.** (Eng) Ho, H. C. (M. and H. Dept. Inst. Radiology and Oncology, Queen Elizabeth Hosp., Kowloon, Hong Kong); Ng, M. H.; Kwan, H. C. *Br J Cancer* 37(3): 356-362; 1978.

Horizontal and longitudinal studies were performed with nasopharyngeal carcinoma (NPC) patients before and after radiotherapy (RT) and with their family members, who have a higher risk of this disease than family members of patients with other cancers. Sera or plasma were obtained from Chinese NPC patients, their apparently healthy family members, and Tunisian and Caucasian NPC patients. Regardless of the ethnic origin of the patient, NPC appeared to stimulate the production of IgA antibodies against viral capsid antigen (VCA). There was, however, a wider scatter in IgA anti-VCA titers than in titers of IgG reactivity. The IgA anti-VCA antibodies were detected at high frequency and titers in sera from NPC patients but only rarely in sera from control subjects. Most relapse-free survivors tested 1-12 yr after RT sustained a detectable level of IgA anti-VCA. Serum titers of IgA anti-VCA remained relatively unchanged in individual NPC patients after RT, regardless of the course of the disease. Furthermore, these antibodies were detected in serum from one individual 9 mo before NPC, and the titer rose concomitantly with its clinical onset. Titers of IgA anti-VCA in multiple serum specimens from individual NPC patients and in sera from different NPC patients did not correlate with titers of IgG anti-VCA or serum IgA protein concentrations. Apparently healthy persons with detectable IgA anti-VCA tended to aggregate in families of NPC patients. The distribution of siblings of these families showed the binomial distribution expected for an autosomal recessive trait, implying the involvement of an autosomal recessive gene in the IgA anti-VCA response. (14 refs)

78-2936 **Evidence for a Specific Immunological Response Against Reverse Transcriptase (RT) as Evidenced by Natural Ig Found on the Membrane of Leukocytes from Patients with Leukemia.** (Eng) Saxinger, W. C. (Lab. Tumor Cell Biology, NCI, Bethesda, MD, 20014); Jacquemin, P. C.; Gallo, R. C. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Disease, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York Elsevier/North Holland Biomedical Press): 503 pp.; 466-470; 1978.

Purified IgG was extracted from the blood cells of leukemic patients and tested for immunological responsiveness against the reverse transcriptases (RTs) of various C-type RNA tumor viruses. The amount of antibody required for 50% inhibition of purified RT was investigated using antibody preparations from two patients with CML and one with AML. With the two CML patients, the most neutralized enzyme was feline leukemia virus RT; however, the antibodies from the second CML patient showed greater cross-reactivity with the RT's from other mammalian oncornaviruses than did the antibodies from the first patient. The AML patient's antibodies reacted only with simian sarcoma virus and human HL23 virus RT. The amount of IgG required for neutralization of the viral RTs was 10 to 100 times less than the amount necessary with laboratory generated hyperimmune sera. In a preliminary survey of membrane-associated anti-RT IgG, 5 μg of IgG were obtained from patients with CML, AML, AMML, and lymphoid leukemias and from normal buffy-coated cells and bone marrow cells and compared for RT neutralization. A total of 10/15 samples from CML patients resulted in a mean neutralization of 65% of the RT; 9/19 AML and AMML samples produced 40% neutralization; 3/13 lymphoid leukemia samples produced 33% neutralization; and with the buffy-coated and normal marrow cells, 7/23 samples produced 55% inhibition. The presence of natural antibodies that neutralize purified viral RT provides new evidence for the presence of viral information in association with some human leukemias. (18 refs)

78-2937 **Cross-linked Surface Ig Attaches to Actin.** (Eng) Flanagan, J. (Medical Res. Council, Lab. Molecular Biology, Hills Rd., Cambridge, England); Koch, G. L. *Nature* 273(5660): 278-281; 1978.

Studies were conducted to determine whether surface immunoglobulin (Ig) was attached to actin isolated from lymphocytes and P3 myeloma cells. The surface Ig was marked by reaction with ^{125}I-labeled rabbit antimouse Ig antibody (RaM Ig), either as the F(ab)$_2$ or Fab fragments. Actin was separated from other cell components by the myosin affinity technique. The amount of binding between actin and surface Ig was very low under non-cross-linking conditions but the binding increased after the application of capping conditions. Conditions that prevented capping but not patching did not preclude the attachment of actin, suggesting that the crucial step in the attachment was the cross-linking of the surface Ig. The possibility that the cross-linked surface Ig became attached to the actin after cell lysis was examined by carrying out the lysis and myosin extraction over a 20-fold dilution of cells. The proportion of surface Ig bound to the myosin remained constant, indicating that the attachment of the cross-linked surface Ig to the actin filaments took place in the intact cell. It is postulated that the cross-linking leads to attachment because of its effect on a preexisting equilibrium between surface components and microfilaments. (10 refs)

78-2938 **Lacunar Cells of Nodular Sclerosing Hodgkin's Disease: An Ultrastructural and Immunohistologic Study.** (Eng.) Anagnostou, D. (Evangelismos Hosp., Athens, Greece) Parker, J. W.; Taylor, C. R.; Tindle, B. H.; Lukes, R. J. *Cancer* 39(3): 1032-1043; 1977.

Tissues from 2 patients with nodular sclerosing Hodgkin's disease were studied by light and electron microscopy in conjunction with immunohistologic and cytochemical staining. The lipid in the cytoplasm of lacunar cells was probably responsible for the distinctive lacunar appearance of the cells. Marked morphologic similarities between blast cells resulting from mitogen stimulation of lymphocytes in vitro, immunoblasts in reactive lymphoid tissues, and mononuclear Hodgkin's cells in Hodgkin's disease suggested that all three cell types may result from lymphocyte transformation. There was an apparent developmental sequence from lymphocyte to transformed lymphocyte to the abnormal mononuclear Hodgkin's cell, with further progression (through increasing size and nuclear lobulation) to the lacunar cell or, alternatively, to the diagnostic Reed-Sternberg cell. This proposed sequence was supported by immunoperoxidase studies that demonstrated cytoplasmic immunoglobulin in mononuclear Hodgkin's cells, lacunar cells, and Reed-Sternberg cells. The relationship between these cells was further supported by the findings of both κ and λ chains, a pattern not seen in reactive transformed lymphocytes. (39 refs.)

78-2939 **Familial Lymphoma.** (Eng) Fradis, M. (Dept. Otolaryngology, Rothschild Univ. Hosp., Aba Khoushy Sch. Medicine, Haifa, Israel); Podoshin, L.; Zismann, D. *Ear Nose Throat J* 57(7): 310-314; 1978.

Three families in which lymphoma of the head and neck region was found in the mother and one of her children are reported. The mothers/children (2 girls, 1 boy) were aged 40/12, 40/15, and 57/15 yr, respectively. The time lapse between discovery of the lymphomas in the mother and child was 8, 2, and 4 yr, precluding a viral etiology. The most likely explanation is a genetic one, even though no chromosome abnormalities were found. (20 refs)

78-2940 **Studies of Japanese Burkitt's Lymphoma. Part 1. Establishment of a Japanese Burkitt's Lymphoma Cell Line.** (Jpn) Kishimoto, H. (Dept. Internal Medicine, Okayama Univ. Medical Sch., Okayama, Japan). *Jpn J Clin Hematol* 19(2): 93-99; 1978.

A new cell line (JBL) was established from the pleural effusion of a 29-yr-old Japanese woman with Burkitt's lymphoma. She was Epstein-Barr virus (EBV)-seropositive, but the JBL cells and the lymphoma cells were EBV genome-free on repeated testing. Most cells from both sources had monoclonal surface IgM with λ light chains. The JBL line grew in suspension with a doubling time of 30 hr, and it consisted of primitive lymphoid cells with large nuclei, prominent nucleoli, and a vacuolated cytoplasm. The JBL cells had a pseudodiploid karyotype with a large subtelocentric marker involving chromosome 11. They lacked the chromosome 14 translocation characteristic of African Burkitt's lymphoma. (20 refs)

78-2941 **Ultrastructural Study of 28 Cases of Ewing's Sarcoma: Typical and Atypical Forms.** (Eng) Llombart-Bosch, A. (Departamento de Patologia, Facultad de Medicina, Paseo al Mar, 15, Valencia, 10, Spain); Blache, R.; Peydro-Olaya, A. *Cancer* 41(4): 1362-1373; 1978.

The results of an ultrastructural study of 28 cases of Ewing's sarcoma are presented. These tumors were diagnosed in 22 females and 6 males, aged 1-25 yr. Morphological diversity within the group allowed the differentiation of a conventional form of the disease (18 women, 3 men), and an atypical variant form (4 women, 3 men). The former was characterized by blastemic cells and secondary degenerative cells, and the structure of the latter had either an immature mesenchymal or histiocytic appearance. The atypical variant was characterized by variability in size and a grooved nucleus that contained prominent nucleoli. The amount of glycogen in the cytoplasm varied from cell to cell, and a comparison with the conventional form revealed more highly differentiated structures in the variant. The variant cells also contained cytoplasmic filaments, mitochondrial complexes, desmosomiclike junctions, and profiles of endoplasmic reticulum. There were no transitional forms between the conventional and the atypical variants. No clinical or anatomical differences could be established between either variant of Ewing's sarcoma. Because of the varying amounts of glycogen in these Ewing's sarcoma cells and the presence of glycogen in undifferentiated mesenchymal tumors and malignant hemoblastosis cells, it is suggested that this commonly used diagnostic feature of Ewing's sarcoma is of restricted value. (43 refs)

78-2942 **Leiomyosarcoma of the Scrotum: A Case Report with Electron Microscopy.** (Eng) Johnson, S. (Dept. Pathology, Univ. Texas Health Science Center, Southwestern Sch. Medicine, Dallas, TX, 75235); Rundell, M.; Platt, W. *Cancer* 41(5): 1830-1835; 1978.

The case of an 89-yr-old man with a leiomyosarcoma of the right scrotum is presented. The tumor, which measured 3 x 2.5 x 2 cm, had been present as a slowly enlarging mass for 3 mo. Light microscopy demonstrated the typical interlacing fascicles of neoplastic cells with eccentric cigar-shaped nuclei, and electron microscopy confirmed the smooth muscle origin of the tumor. This is only the fifth reported case of leiomyosarcoma confined to the scrotal wall. (19 refs)

78-2943 **Malignant Fibrous Histiocytoma and Pleomorphic Sarcoma in Association with Medullary Bone Infarcts.** (Eng) Galli, S. J. (Dept. Pathology, Massachusetts General Hosp., Boston, MA, 02114); Weintraub, H. P.; Proppe, K. H. *Cancer* 41(2): 607-619; 1978.

A malignant fibrous histiocytoma arose in the proximal tibia of a 40-yr-old man who had multiple medullary bone infarcts involving the distal femora and the tibiae. Despite amputation and chemotherapy, widespread metastases developed and the patient died 19 mo after surgery. A pleomorphic sarcoma, probably representing an anaplastic malignant fibrous histiocytoma, arose in association with a single medullary infarct in the proximal humerus of a 33-yr-old woman. She remains well without evidence of disease 5 yr after treatment by radical radiotherapy followed by shoulder disarticulation. Sarcoma arising in association with bone infarction is a rare entity. In the 16 known cases, including the present 2, the sarcomas arose in the tibia in 9, the femur in 6, and the humerus in 1. The av age of the patients was 49 yr, and 13 were men. All but two had multiple bone infarctions. Four of the patients had caisson disease, 3 apparently had hereditary bone dysplasia, 1 had sickle cell disease, and 8 had infarcts of unknown etiology. Most patients have had a rapidly fatal outcome. Thirteen of the sarcomas were fibrosarcomas or malignant fibrous histiocytomas, both rare primary bone tumors. Analysis of the published data on bone infarction-related sarcomas suggests that the risk of developing a sarcoma is greatest in infarcts with large medullary components. (30 refs)

78-2944 **Ultrastructural Observations on the Histogenesis of Alveolar Rhabdomyosarcoma.** (Eng) Churg, A. (Dept. Pathology, Univ. Chicago, 950 E. 59th St., Chicago, IL, 60615); Ringus, J. *Cancer* 41(4): 1355-1361; 1978.

An alveolar rhabdomyosarcoma (ARMS) from the left forerm of a 9-yr-old boy was studied ultrastructurally, with particular emphasis on the detection of myofilaments. The bulk f the tumor was composed of small polygonal cells containng polyribosomes, short strands of rough endoplasmic eticulum, and variable amounts of glycogen; the cells were oined by small desmosomelike structures. Similar cells, as vell as larger cells apparently derived from the smaller ones, vere observed along the septa; the larger forms developed a copious cytoplasm and occasionally produced myofilaments. Some of these cells were separated from the septa by basement membranes. Giant cells were present in the alveolar spaces; myofilament bundles were not present in these cells and they were not surrounded by a basement membrane. The septa were mostly composed of collagen and fibroblasts. These observations suggest that the ARMS was mostly epitheliallike; it may correspond to the organization of mesenchymal cells at the stage of somite differentiation. Since this tumor has several features in common with Ewing's sarcoma, it may also be a proliferation of neoplastic mesenchymal cells corresponding to those seen early in embryogenesis and showing no discernible differentiation. (19 refs)

78-2945 **Mycosis Fungoides Evolving to Myelomonocytic Leukemia.** (Eng) Lofgren, R. K. (Dept. Dermatology, Mayo Clinic and Mayo Foundation, Rochester, MN, 55901); Wiltsie, J. C.; Winkelmann, R. K. *Arch Dermatol* 114(6): 916-920; 1978.

Two cases of long-standing mycosis fungoides (MF) developing 5 and 15 yr later into acute myelomonocytic leukemia (AML) are reported. The two female patients (aged 50 and 57 yr) had been treated with topical mechlorethamine and focal radiation throughout the course of the MF. One patient had also received chlorambucil (2 mg/day for 5 mo). Five literature cases of myelogenous leukemia as the terminal event of MF are also reported. The duration of the MF was 2-3, 5, 7, 11, and 18 yr, and treatment comprised various combinations of x-rays, grenz rays, iv mechlorethamine, urethan, corticotropin, and cyclophosphamide. Chronic myelogenous, acute myeloblastic, myeloid, chronic granulocytic (or leukemoid reaction), and myeloid leukemia were the types that resulted. By depressing the immune surveillance system, the therapy for MF may participate in the development of leukemia; however, a definite relationship to therapy could not be established. The development of leukemia in the two present cases may be a complication of therapy, a manifestation of some predisposing factor common to AML and MF, or a result of the direct evolution of MF. (13 refs)

78-2946 Familial (Erythro)-Leukemia: 4 Cases of DiGuglielmo's Syndrome in Close Relatives (Meeting Abstract). (Eng) Nissenblat, M. (Johns Hopkins Oncology Center, Johns Hopkins Hosp., Baltimore, MD, 21205); Bias, W.; Borgaonkar, D.; Dixon, S. *Proc Am Assoc Cancer Res* 19: 412; 1978. (no refs)

78-2947 **Aplastic Anemia and Acute Leukemia in Two Siblings.** (Jpn) Sawa, F. (Dept. Pediatrics, Toho Univ. Sch. Medicine, Toho, Japan); Shinomiya, N.; Maruyama, S.; Nakagawa, T.; Tsukimoto, I.; Nakayama, K. *Jpn J Clin Hematol* 19(2): 180-186; 1978.

Case reports are presented for a sister and brother who developed idiopathic aplastic anemia and acute leukoblastic leukemia, respectively. The girl was 23 mo old at the time of diagnosis, the boy 7 mo old. No evidence of a preleukemic stage was found in the sister, who died of an intracranial hemorrhage due to a traffic accident within 3 yr of the diagnosis. In the course of her disease, she had three intussusception episodes that were treated sucessfully with high-pressure enemas. Although complete remission was induced in the boy with VMP therapy (vincristine, mercaptopurine, prednisone), he died of bone marrow relapse, meningeal infiltration, intracranial hemorrhage, and sepsis 1 yr after diagnosis. No blood disease or malignant neoplasms were found in the family of these siblings, and the family members had a normal karyotype. At age 4 yr, the mother had been exposed to the atomic bomb radiation in Hiroshima (2,000 meters from the hypocenter). (28 refs)

78-2948 **Breast Cancer and Acute Leukemia: Report of 24 Cases and Review of the Literature.** (Eng) Rosner, F. (Hematology Div., Queens Hosp. Center, Long Island Jewish-Hillside Medical Center, 82-68 164 St., Jamaica, NY, 11432); Carey, R. W.; Zarrabi, M. H. *Am J Hematol* 4(2): 151-172; 1978.

The association of acute leukemia and breast cancer is reviewed, and the possible etiological role of breast cancer treatment in the development of acute leukemia is examined. Twenty-four cases of breast cancer + acute leukemia and three cases of breast cancer + chronic myelocytic leukemia are briefly described, and an additional 54 cases of acute leukemia and 13 of chronic myelocytic leukemia associated with breast cancer are reviewed from the literature. The mean interval between the diagnosis of breast cancer and the occurrence of acute leukemia was 6.9 yr. In nine patients, the diseases occurred simultaneously or within 1 yr of each other. Thirteen patients received no postmastectomy radiotherapy or chemotherapy, and the occurrence of acute leukemia 1-23 yr later cannot be attributed to breast cancer therapy. Forty-seven patients received postoperative radiotherapy to the mastectomy site. Combination chemotherapy was given to eight patients, three of whom were also treated with radiotherapy. Acute leukemia is estimated to occur in patients treated for breast cancer with a sevenfold increased frequency over the expected number. This increased incidence may be due to an increased risk of a second neoplasm in patients with a primary tumor, or it may be related to the radiotherapy and/or chemotherapy administered to treat the breast cancer. Spontaneous leukemia in breast cancer patients who received neither radiation nor chemotherapy probably has a different mode of genesis than that developing in patients who received these treatments. (100 refs)

78-2949 **Lobular Carcinoma In Situ on a Breast Fibroadenoma.** (Fre) Parache, R. M. (Centre Alexis-Vautrin, 54500 Vandoeuvre, France); Poisson, P.; Barlier, C. *Arch Anat Cytol Pathol (Paris)* 26(1): 47-49; 1978.

Lobular carcinoma in situ developed within a breast fibroadenoma in a 43-yr-old woman. Less than 40 such cases have been reported in the literature. (12 refs)

78-2950 **Familial Breast Cancer: Report of a Family Pedigree.** (Eng) Armstrong, A. E. (Dept. Community Medicine, Univ. Coll. Hosp. Medical Sch., London WC1, England); Davies, J. M. *Br J Cancer* 37(2): 294-307; 1978.

Following a report of several relatives suffering from breast cancer, the occurrence of neoplasms in three generations of a large family was carefully checked. Members of 1/8 branches had a high incidence of breast cancer, with six women being affected, four of them under the age of 40. As well as early onset, these women presented other features typical of breast cancer families: bilateral breast cancer, other second primary tumors, ovarian cancer in the daughter of one affected patient, and benign breast disease in the sister of another. The chance of the young women in the fourth generation developing breast cancer must be judged very high, possibly higher than the av 30% risk of developing the disease before the age of 40 deduced previously. 78-2951 **Endocrinic Correlates in Familial Breast Cancer (Meeting Abstract).** (Eng) Harris, R. E. (Creighton Univ. Sch. Medicine, Omaha, NB, 68178); Fishman, J.; Fukushima, D. K.; Maloney, K.; Carmody, L.; Lynch, J. F.; Marrero, K. *Proc Am Assoc Cancer Res* 19: 411; 1978. (no refs)

78-2952 **Squamous Carcinoma of the Breast.** (Eng) Hasleton, P. S. (Dept. Pathology, Univ. Hosp. South Manchester, Manchester, England); Misch, K. A.; Vasudev, K. S.; George, D. *J Clin Pathol* 31(2): 116-124; 1978.

Two women, one aged 64 and one aged 63 yr, developed squamous cell carcinoma of the breast. In each case, no lymph node invasion was found, the nipple was histologically normal, and no other type of cancer was found in the specimen. Histological evaluation suggested that the first tumor arose in a epidermoid cyst and that the second arose from metaplastic ductal epithelium. The former tumor also had a pseudosarcomatous stroma. It was concluded that myoepithelial cells did not play a role in the histogenesis of these tumors. A literature review of similar tumors is presented. (21 refs)

78-2953 **Ultrastructural Comparison of Differentiation of Stem Cells of Murine Adenocarcinomas of Colon and Breast with Their Normal Counterparts.** (Eng) Pierce, G. B. (Dept. Pathology, Sch. Medicine, Univ. Colorado, 4200 E. Ninth St., Denver, CO 80262); Nakane, P. K.; Martinez-Hernandez, A.; Ward, J. M. *J Natl Cancer Inst* 58(5): 1329-1345; 1977.

Two F344 rats with chemically induced transplantable adenocarcinomas of the colon were given ^{3}H-thymidine pulses, and autoradiography with electron microscopes was used to compare the degrees of differentiation of the tumor and colon stem cells. The most differentiated portions of the tumor had acini composed of vacuolated, mucous, and argentaffin cells in various stages of differentiation. Vacuolated and mucous cells incorporated ^{3}H-thymidine and corresponded in degree of differentiation to that of their labeled normal counterparts in the normal colon. An exceedingly undifferentiated labeled cell was identified in the tumor and crypts; this may be an undifferentiated colon stem cell that differentiates into vacuolated and mucous stem cells and/or argentaffin cells. Stem cells of normal mammary epithelium and malignant stem cells of spontaneous mammary adenocarcinomas of C3H mice had comparable degrees of differentiation. Since normal stem cells were as undifferentiated as the least-differentiated malignant stem cells, there is no need to postulate dedifferentiation as a mechanism of carcinogenesis. (40 refs.)

78-2954 **Malignant Mixed Tumors of the Mammary Gland.** (Ger) Hager, J. (Pathologisches Institut der Universitat, Mullerstrasse 44, A-6020 Innsbruck, Austria); Lederer, B. *Zentralbl Allg Pathol* 121(6): 522-525; 1977.

A malignant mixed carcinosarcoma with mesenchymal, epithelial, chondroosteoid, and myxomatous structures was found in a 34-yr-old woman. Histological examination revealed the myogenic origin of the tumor. (18 refs.)

78-2955 **Focal Nodular Hyperplasia of the Liver and Oral Contraceptive Usage.** (Ger) Gogler, H. (Chirurgische Klinik und Poliklinik, Klinikum Charlottenburg der Freien Universitat, Spandauer Damm 130, D-1000 Berlin 19, W. Germany); Beger, H. G.; Zuschneid, W.; Bucherl, E. S.; Vogel, M. *Chirurg* 49(3): 172-179; 1978.

Benign liver tumors occurred in three young women who had taken oral contraceptives for 6, 7, and 16 yr, respectively. Histologically, focal nodular hyperplasia was found in these women. Pain in the upper abdomen and general weakness were the main symptoms. Selective angiography is the most valuable diagnostic procedure. Fifty-eight cases from the literature are also reported. (15 refs)

78-2956 **Hepatocarcinoma and Oral Contraceptives (Letter to Editor).** (Eng) Trias, R. (Pathology Dept., Hospital de la Santa Creu i Sant Pau, Autonomous Univ., Barcelona, Spain); Rius, X.; Autonell, J.; Algaba, F. *Lancet* 1(8086): 821; 1978.

A tumor showing the classical features of hepatocarcinoma was removed from a 28-yr-old woman who had been taking ethinylestradiol (50 μg) and norgestrel (0.5 mg) for 13 mo for menstrual disorders. Connective tissue and vascular lesions of this type are associated with focal nodular hyperplasia, the incidence of which is increasing in women on oral contraceptives. (6 refs)

78-2957 **Liver Cell Carcinoma Associated with Oral Contraceptives.** (Fre) Leclere, J. (Service d'Endocrinologie et Medecine E, C.H.U. de Nancy, Hopital de Brabois, F 54500 Vandoeuvre-les-Nancy, France); Meot, B.; Marchal, F.; Mizrahi, R.; Collard, F.; Rauber, G.; Hartemann, P. *Ann Endocrinol (Paris)* 38(6): 361-362; 1977.

A malignant hepatic tumor occurred in a 42-yr-old woman who had been taking oral contraceptives for 10 yr. Histologically, it was a well-differentiated diffuse carcinoma. The presence of benign and malignant tumor tissue in the livers of women on steroid contraceptives supports the theory that hormones have a role in the development of hepatic lesions. (4 refs)

78-2958 **Endometrial Hyperplasias and Their Relationship to Endometrial Carcinoma.** (Ger) Ritzmann, H. (Universitats-Frauenklinik, D-7800 Freiburg im Breisgau, W. Germany); Hillemanns, H. G. *Arch Gynaekol* 223(4): 345-355; 1977.

Hyperplastic alterations were studied in the peripheral endometrium of 196 women who underwent hysterectomy for uterine carcinoma and in 208 control women of the same age who underwent hysterectomy for diseases other than carcinoma. The av age of the carcinoma patients who had adenomatous hyperplasia (HP) of the peripheral endometrium was 52.2 yr, that of all carcinoma patients was 61.9 yr, and that of the carcinoma patients with glandular cystic HP was 60.8 yr. The incidence of adenomatous HP of the peripheral endometrium was 38/196, that of glandular cystic HP 35/198. Cyclic changes or slight endometrial proliferation was seen in 47 cases, atrophy in 76. The incidence of adenomatous HP was 31.5% in carcinoma patients and 4.5% in controls aged 45-49 yr, vs 26.4% and 1.6%, respectively, in those aged 50-54 yr, 25% and 0% in those aged 55-59 yr, 13.4% and 0% in those aged 60-65 yr, and 7.7% and 3.8% in those aged >65 yr. The incidence of glandular cystic HP was 10.5% in carcinoma patients and 6.1% in controls aged 45-49 yr, 11.7% and 4.9%, respectively, in those aged 50-54 yr, 15.9% and 0% in those aged 55-59 yr, 25% and 16.1% in those aged 60-65 yr, and 20.5% and 3.8% in those aged >65 yr. The simultaneous occurrence of adenomatous HP and endometrial carcinoma suggests that this form of HP is precancerous. Before menopause, glandular cystic HP does not seem to play any role in the development of endometrial carcinoma. The cause of the high frequency of glandular cystic HP in postmenopausal women is unknown. (36 refs)

78-2959 **A Benign Serous Ovarian Cystadenoma Studied by Chromosome and Quantitative DNA Analysis.** (Eng) Wager, J. (Dept. Gynecology, Huddinge Hosp., Stockholm, Sweden); Granberg, I.; Vass, L.; Auer, G. *Acta Cytol (Baltimore)* 21(6): 774-776; 1977.

Chromosome and quantitative DNA analyses were performed on a benign serous ovarian cystadenoma removed from a 78-yr-old woman with a 3-yr history of abdominal enlargement. Only a few metaphases were noted in the primary tumor and ascitic fluid, and all were diploid. Cells from the cystic fluid, however, contained 50% diploid, 47% triploid, and 3% hectaploid metaphases. DNA analyses of cells taken from the tumor wall or cystic fluid showed 94% with diploid DNA values and 6% with tetraploid values. In cells from the cystic fluid, 60% had DNA values in the diploid region, 36% in the triploid region, and 4% in the hectaploid region. Karyotyping of cells in the cystic fluid indicated that of four near triploid metaphases examined, at least one large submedian marker chromosome was found. Cytology slides from the cystic fluid showed large atypical groups of cells with marked nucleoli. It is suggested that the triploid cells in the cystic fluid represent an abnormal population, possibly a developing step in carcinogenesis. (2 refs)

78-2960 **Incidence of Subclinical Metastasis in Stage I and II Ovarian Carcinoma.** (Eng) Piver, M. S. (Dept. Gynecologic Oncology, Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263); Barlow, J. J; Lele, S. B. *Obstet Gynecol* 52(1): 100-104; 1978.

The incidence of unsuspected, subclinical metastasis to the diaphragm, retroperitoneal lymph nodes, and omentum and of positive peritoneal cytology was determined in 31 consecutive patients referred to Roswell Park Memorial Institute (Buffalo, New York) from 1975 to 1977, 5 additional patients referred recently, and cases from the literature, all with Stage I or II ovarian carcinoma. Of the women with presumed Stage I ovarian cancer, 11.3% were found to have diaphragmatic metastases, 13.3% had aortic lymph node metastases, 8.1% had pelvic lymph node metastases, 3.2% had omental metastases, and 32.9% had malignant peritoneal washings. In State II ovarian cancer, 23% had diaphragmatic metastases, 10.0% had aortic lymph node metastases 0% had omental metastases, and 12.5% had malignant peritoneal washings. These are minimal figures for subclinical metastasis, especially in those cases in which only selected aortic and pelvic node biopsies were carried out. (20 refs)

78-2961 **Morphology and DNA Content of Cultures from Normal and Dysplastic Epithelium, Carcinoma In Situ, and Carcinoma of the Cervix Uteri.** (Ger) Ebeling, K. (Zentralinstitut fur Krebsforschung, Akademie der Wissenschaften der DDR, Lindenberger Weg 80, DDR-1115 Berlin-Buch, E. Germany); Krug, H.; Bilek, K. *Arch Geschwulstforsch* 48(1): 17-34; 1978.

The amount of DNA in cell nuclei was studied cytophotometrically in explant cultures from human normal and dysplastic squamous epithelium, carcinoma in situ, and squamous epithelial carcinoma of the uterine cervix. The mean DNA values, expressed in working units (WU; product of the nucleus surface x extinction), were 39.32 WU in dysplastic epithelium, 33.42 WU in carcinoma in situ, and 38.46 WU in squamous epithelial carcinoma, values significantly higher ($p < 0.05$) than that for normal squamous epithelium (25.01 WU). The differences in DNA levels among the dysplasia, carcinoma in situ, and carcinoma were not significant. Aneuploidy, polyploidy, and a predominance of periploidy were seen in the atypical cervical epithelium. As opposed to the normal epithelial cells which grew in monolayers, cells in the atypical epithelium and carcinoma cultures lost their adhesiveness, which led to loss of the monolayer structure and to overlapping of the cells as the most distinct characteristics of atypia. (35 refs)

78-2962 **Cervical Adeno-carcinoma and Partial Hydatidiform Mole.** (Eng) Mazor, B. (Dept. Obstetrics and Gynecology, Carmel Hosp., Haifa, Israel); Bar-Am, A.; Deligdish, L. *Acta Obstet Gynecol Scand* 57(3): 273-276; 1978.

A 39-yr-old multiparous Jewish woman was found to have a polypoid cervical well-differentiated cervical adenocarcinoma. At hysterectomy 2 wk after excision of this tumor, an unsuspected partial hydatidiform mole was found. Granulation tissue with squamous metaplasia and mild dysplasia of the cervix uteri were also found. At follow-up 4.5 yr later, there was no evidence of metastases. The hormonal influence of the molar pregnancy, with its marked trophoblastic hyperplasia, could have triggered transformation of a glandular polyp into the adenocarcinoma. The dysplastic proliferation of the cervical epithelium could also have been influenced by the trophoblastic hyperactivity of the partial mole. (11 refs)

78-2963 **Morphologic Evidence for Retrovirus Production by Epithelial Cells Derived from a Human Testicular Tumor Metastasis: Brief Communication.** (Eng) Bronson, D. L. (Dept. Urologic Surgery, Univ. Minnesota Coll. Health Sciences, Box 394, Mavo Memorial Bldg., 420 Delaware St. SE, Minneapolis, MN, 55455); Ritzi, D. M.; Fraley, E. E.; Dalton, A. J. *J Natl Cancer Inst* 60(6): 1305-1308; 1978.

Ultrastructural examination of primary and subcultured epithelial cells established in vitro from an abdominal metastasis of a human testicular tumor revealed particles with the morphology of retroviruses. These structures, found only after extensive scanning of the cells, were observed budding from microvilli or the outer cell membrane and as extracellular particles. Virus particle production was stimulated by incubation of the cells in culture medium containing 5-iodo-2′-deoxyuridine and dexamethasone. (21 refs)

78-2965 **Mortality Among Women First Employed Before 1930 in the U. S. Radium Dial-Painting Industry. A Group Ascertained from Employment Lists.** (Eng) Polednak, A. P. (Center Human Radiobiology, Radiological and Environmental Res. Div., Argonne Natl. Lab., Argonne, IL, 60439); Stehney, A. F.; Rowland, R. E. *Am J Epidemiol* 107(3): 179-195; 1978.

To determine the possible effects of exposure to radium on the development of cancer, a cohort of 634 women who worked in the US radium dial-painting industry between 1915 and 1929 was studied. Compared with mortality rates for all US white women, mortality from all cancers (84 observed vs 43.36 expected), bone cancer (22 vs 0.3), cancer of other and unspecified sites (18 vs 2.6), cancer of the colon (10 vs 5.0) was increased significantly among the study population. The number of deaths attributed to all cancers, bone cancer, and leukemia and diseases of the blood and blood-forming organs was significantly lower among women first exposed to radium after 1924 than among those first exposed before 1924. Mortality ratios were markedly lower for the 1965-1975 time period relative to earlier time periods, and the number of deaths from leukemia and diseases of the blood was significantly greater than expected during the period before 1945. Mortality ratios for bone cancer were higher among women aged < 20 yr at exposure than among those $\geqslant 20$ yr old at exposure. Increased mortality from all causes was observed only among women with radium body-burdens $\geqslant 50\ \mu$Ci; only the number of deaths due to colon cancer was greater than the number expected (5 vs 1.72) in those with body-burdens of $< 50\ \mu$Ci. (56 refs)

78-2966 **Mortality Among Individuals Occupationally Exposed to Benzene.** (Eng) Ott, M. G. (Dow Chemical Co., Midland, MI); Townsend, J. C.; Fishbeck, W. A.; Langner, R. A. *Arch Environ Health* 33(1): 3-10; 1978.

The long-term mortality experience among 594 individuals occupationally exposed to benzene was studied using a retrospective cohort design. Excluding 53 individuals who were also exposed to arsenicals, asbestos, or vinyl chloride, no statistically significant increases over US white male mortality rates were found among the benzene workers in any cause-of-death category. When the 53 patients were included, there were higher than expected incidences of anemia (2 vs 0.2 expected) and leukemia (3 vs 0.8). The records of these five decedents were examined in detail. One of those who died of leukemia had also been exposed to nitrobenzene, bromine, and vinyl and vinylidene chloride, another had been employed previously in the manufacture of veneer, and the third had probable exposure to p-chlorophenol, ethyl chloride phenetidine, acetic anhydride, and phenacetin dus Therefore, although the observed incidence of leukemi in the study group significantly exceeded the expecte incidence, a retrospective assessment of the possibl relationship to benzene exposure is difficult. (11 refs

78-2967 **Non-occupational Exposure to Asbestos and Malignant Mesothelioma in Females.** (Eng Vianna, N. J. (Bureau Occupational Health and Chronic Disease Res., New York State Dept. Health, Empire State Plaza Tower Building, Albany, NY, 12237); Polan, A. K. *Lancet* 1(8073): 1061-1063; 1978.

The records of 52 female residents of New York State who died between 1967 and 1977 with histologically confirmed malignant mesothelioma were studied to assess the possibility that household exposure to asbestos might be a major risk factor for the disease. The subjects were all Caucasian, and their mean age at diagnosis was 60.2 yr. Six subjects had worked at asbestos-related occupations, and 10 subjects had husbands and/or fathers who worked at asbestos-related occupations. Seventeen subjects had fathers and/or husbands whose occupations were associated with pneumoconioses other than asbestosis. A significantly greater number of the mesothelioma cases had husbands or fathers who worked in asbestos-related industries than did controls who had died during the same period from causes other than cancer. The relative risk for this factor was 10. The frequency of parental cancer, especially gastrointestinal malignancy, was also significantly greater for the cases than for the controls. There were no differences between subjects and controls in race, religion, duration of married life, other illnesses requiring hospital admission, personal histories, or socioeconomic status. The data suggest that women run the risk of malignant mesothelioma not only if they work in asbestos-related industries but also if they are indirectly exposed to environmental asbestos. The possibility of a genetic predisposition to malignant mesothelioma is also suggested. (25 refs)

78-2968 **Risk of Bronchial Carcinoma in Persons with Tuberculotic Lesions.** (Ger) Trefny, J. (Forschungsinstitut fur Tuberkulose und Respirationskrankheiten, 8 Bulovka, CS-180 71 Prague, Czechoslovakia). *Z Erkr Atmungsorgane* 149(3): 313-318; 1977.

A study was made of the incidence of bronchial carcinoma n persons with tuberculotic and fibrotic (probably posttuberculotic) pulmonary lesions and in the general population 177,000) of three districts of Prague during 1965-1967 and 1970-1972. Bronchial carcinoma was found n 504 patients (447 men and 57 women), and tuberculotic or posttuberculotic lesions were found in 134 patients. Relative to the nonstandardized general population aged ≥ 15 yr, the incidence of bronchial carcinoma was 355.5/100,000 in men and 31.9/100,000 n women with tuberculotic lesions, vs 71/100,000 n men and 8.7/100,000 in women without such lesions. The corresponding incidences in the age- and sex-standardized population were 176.4/100,000 in men and 8.9/100,000 in women with tuberculotic lesions and 5.6/100,000 in men and 8.6/100,000 in women without such lesions. The difference in the incidences of bronchial carcinoma in persons with and without tuberculotic lesions remained significant even after the influence of smoking was eliminated. The autopsy findings in 94 carcinoma patients with tuberculotic lesions revealed a topological link between the two pathologies in 34% and homolateral neoplastic and tuberculotic processes in 42%. The tuberculotic lesions appeared fibrotic in 77%, and active tuberculosis was found in 3%. The findings indicate that the probability of bronchial carcinoma is at least twice as high in persons with tuberculotic or fibrotic lesions than in those without such lesions. No relationship was found between the tuberculotic lesion and the histological type of the carcinoma. (6 refs)

78-2973 **Prostatic Cancer: Mortality and Incidence Rates by Race and Social Class.** (Eng) Ernster, V. L. (G. W. Hooper Foundation, Univ. California, San Francisco, CA, 94143); Selvin, S.; Sacks, S. T.; Austin, D. F.; Brown, S. M.; Winkelstein, W. *Am J Epidemiol* 107(4): 311-320; 1978.

A study was conducted to determine whether the excess rates of prostatic cancer among blacks could be explained by controlling for race or social class. The mortality data consisted of 400 prostatic cancer deaths occurring in Alameda County, California, during 1968-1972; incidence data were drawn from the population-based series of cases (n = 750) for Alameda County included in the National Cancer Survey (1969-1971). Comparison of age-specific mortality and incidence rates by socioeconomic status revealed no gradient for prostatic cancer in either whites or blacks. Excepting age groups over age 80, the black excess risk held up within age-specific comparisons for every socioeconomic level for which sufficient numbers existed for calculating rates. Previous studies on the relationship between socioeconomic status and prostatic cancer are reviewed. (27 refs)

78-2974 **Does Pregnancy Protect Against Ovarian Cancer?** (Eng) Beral, V. (Epidemiological Monitoring Unit, Dept. Medical Statistics and Epidemiology, London Sch. Hygiene and Tropical Medicine, Keppel St., London WC1E 7HT, England); Fraser, P.; Chilvers, C. *Lancet* 1(8073): 1083-1087; 1978.

The relation between the reproductive histories of different populations of women and their subsequent risk of ovarian cancer was examined. When the ovarian cancer mortality ratio for each 5-yr birth cohort in England, Wales, and the US was plotted against the corresponding av completed family size, a striking negative association was seen. The trends in cohort mortality in 20 countries were inversely related to cohort fertility, and the variation in ovarian cancer mortality from one country to another was inversely related to differences in av completed family size between countries. The low rates of ovarian cancer in developing countries corresponded to the generally high fertility rates. In England and Wales, mortality rates from ovarian cancer among women aged 55-64 yr were consistently higher among single vs married women and among the upper vs the lower social classes. The reported variations in ovarian cancer rates in different religious, immigrant, and ethnic groups were also consistent with an inverse relation between the risk of ovarian cancer and family size. The relative risks of ovarian cancer in women with two and four children were calculated to be 2.0 to 1 and 3.1 to 1, respectively. (28 refs)

78-2975 **Oral Contraceptives and Breast Disease. An Epidemiological Study.** (Eng) Kelsey, J. L. (Dept. Epidemiology Public Health and Human Development, Yale Univ. Sch. Medicine, New Haven, CT, 06510); Holford, T. R.; White, C.; Mayer, E. S.; Kilty, S. E.; Acheson, R. M. *Am J Epidemiol* 107(3): 236-244; 1978.

The relationship between the use of oral contraceptives and the development of benign and malignant breast disease, cancer of the ovary, and cancer of the corpus uteri was investigated in a case-control study of 20- to 44-yr-old premenopausal women in several large Connecticut hospitals. The relative risk of breast cancer was not significantly associated with use of oral contraceptives, per se, length of use, age at first use, length of time since first use, or whether sequential or combination pills were used. The relative risk was increased among women who had used only pills containing mestranol, and it was reduced among those who had used both pills containing ethinyl estradiol and those containing mestranol. Consideration of the progestogen content of the pills did not yield any useful results. The relative risk of benign breast disease decreased as a function of length of use of sequential oral contraceptives, but there was no reduction in risk associated with the use of combination pills. The small number of patients studied with cancer of the ovary or corpus uteri did not permit any conclusions to be drawn regarding these tumors. (17 refs)

78-2976 **Familial Association of Breast/Ovarian Carcinoma.** (Eng) Lynch, H. T. (Dept. Preventive Medicine/Public Health, Creighton Univ. Sch. Medicine, Omaha, NB, 68178); Harris, R. E.; Guirgis, H. A.; Maloney, K.; Carmody, L. L.; Lynch, J. F. *Cancer* 41(4): 1543-1549; 1978.

A genetic and statistical analysis was performed on 12 pedigrees that showed familial clustering of breast and ovarian cancer. These pedigrees contained 91 women diagnosed with breast cancer (60), ovarian cancer (28), or both (3). The significant linear decline in estimates of cumulative breast ovarian cancer risk to women with a diminishing genetic relationship to probands and index cases, plus the lack of excessive site-specific cancer risk to male relatives, supported a sex-limited genetic etiology. Breast/ovarian cancer typically occurred at an early age (50.1 yr for breast cancer, 52.4 yr for ovarian cancer), another characteristic of hereditary cancer. Examples of apparent mother-to-daughter and father-to-daughter genetic transmission of proclivity for breast/ovarian carcinoma were prevalent in these pedigrees. Excluding probands and index cases, the estimated cumulative risk of breast/ovarian cancer to daughters of affected mothers was 46% between the ages of 20-80 yr, suggestin that affected mothers were transmitting a deleterious cancer-predisposing gene to approx half their daughters. Eigh sibships involving putative carrier men contained 15 femal progeny over the age of 20. Of these, six have had breast an five have had ovarian cancer. Genetic heterogeneity of transmission must be considered an etiological agent in these families. (22 refs)

78-2977 **Recent Time Trends in Breast Cancer Incidence.** (Eng) DeWaard, F. (Dept. Epidemiology, Inst. Social Medicine, Univ. Utrecht, Utrecht, Netherlands). *Prev Med* 7(2): 160-167; 1978.

Time-trends in the incidence of breast cancer are discusse based on the third volume of "Cancer Incidence in Five Continents." Analysis of the data indicated that the registere age-standardized incidence has increased in almost all countries and populations, in particular in Icelanders, Israel's Sabras (Jews born in Israel), and Hawaiian Japanese. In th Hawaiian Japanese, there is evidence that the rise in incidenc is largely confined to cohorts born after 1905 (nisei who gre up in an American environment). Under these circumstance an increase in body height occurred that set the stage for new somatotype of taller and heavier people. A combinatio of increased wt and height has been shown to increase th risk of breast cancer in various populations (notably, th Japanese) in the peri- and postmenopausal period. The hypothesis that increased height plays a part in the new epidemic among Hawaiian Japanese explains why the incidence ros cohort-wise and has shown a long latency period since migration. (13 refs)

78-2978 **Time-Trend Data of Breast Cancer in Japa Clinicopathological Findings.** (Eng) Sugano, H (Dept. Pathology, Cancer Inst., Tokyo 170, Japan); Sakamoto, G. *Prev Med* 7(2): 168-172; 1978.

The time-trend change in the clinicopathological behavior breast cancer in Japan was analyzed based on 2,965 patien mastectomized at the Cancer Institute Hospital in Tokyo between 1946 and 1976. Various clinicopathological aspec such as age, histological type, tumor size, lymph node metastasis, and survival rates did not change markedly. Howeve an increase in postmenopausal lobular carcinoma and a sligh increase in premenopausal common-type breast cancer we noted over the past 15 yr. Since dietary conditions in Japa have improved greatly during the past 15 yr, it is suggeste that these changes are probably due to the effect of diet a promotor. (10 refs)

78-2979 **Oesophageal Cancer in Indian Jews in Beersheba, Israel (Meeting Abstract).** (Eng) Ode

78-2980 **Comparative Analysis of Incidence of Cancer of Lips, Skin, and Oral Cavity in Bulgaria.** (Bul) Dimova, I. (Cancer Res. Inst., Sofia, Bulgaria). *Onkologiia* 14(4): 174-178; 1977.

The incidence of lip and skin cancer during 1970-1974 and that of cancer of the oral cavity during 1973-1974 were studied in Bulgaria. The ratio of lip cancer to skin cancer averaged 5.7 (3.5 for men, 17.1 for women, 6.8 for urban dwellers, and 5.1 for rural dwellers). The standardized lip cancer morbidity (per 100,000 inhabitants) was 6.1 (10.4 for men, and 1.9 for women, 4.8 for urban dwellers, and 7 for rural dwellers). The standardized skin cancer morbidity was 34.6 (35.3 for men, 33 for women, 34 for urban dwellers, and 34.3 for rural dwellers). The standardized incidence of cancer of the oral cavity was 3.13 (4.01 in men, 2.26 in women, 2.88 in urban dwellers, and 3.48 in rural dwellers). The incidence of skin cancer increased with advancing age. There was no correlation between the lip cancer morbidity and mean annual solar radiation. (8 refs)

78-2981 **Leukemia Morbidity in Two Neighboring Regions of Szczecin Province, Poland.** (Pol) Rybkowski, W. (Oddzial Wewnetrzyny, Szpital u Szczecinie, ul. Sienkiewicza 4 m. 1, 71-311 Szczecin, Poland). *Wiad Lek* 31(5): 323-325; 1978.

Leukemia morbidity was studied in the adult population of two neighboring regions of Szczecin province, Poland, during 1970-1974. The morbidity (per 100,000 inhabitants) was 9.2 in region A (3.8 for acute leukemia, 1.1 for chronic granulocytic leukemia, and 4.3 for chronic lymphocytic leukemia), and 0.8 in region B. The difference is statistically significant. Leukemia morbidity in cattle was 1,758.6/10,000 in region A vs 886.6/10,000 in region B. The findings suggest a common etiology of leukemia in men and cattle. (26 refs)

78-2982 **Epidemiology of Malignant Laryngeal Neoplasms in Lodz, Poland, for the Years 1967-1974.** (Pol) Fajndt, S. (Klinika Laryngologiczna, ul. Kopcinskiego 22, 90-153 Lodz, Poland); Tronczynska, J.; Dyla, S. *Otolaryngol Pol* 31(5): 499-504; 1977.

The epidemiology of malignant laryngeal neoplasms in the city of Lodz, Poland, and in the surrounding region was examined for the years 1967-1974. Men residing in Lodz had the highest incidence, but the male incidence in the surrounding area was high and on the increase. During this period, the greatest number of new cases was found in manual workers. (10 refs)

78-2983 **Characteristic Features of Cancer Epidemiology in Kirgiz Republic, USSR.** (Rus) Saenko, A. I. (Kirgiz Res. Inst. Oncology, Frunze, USSR). *Vopr Onkol* 24(6): 104-109; 1978.

Cancer morbidity in Kirgiz Republic, USSR, is reviewed. Between 1966 and 1976 the incidence of stomach cancer, cervical carcinoma, and lip cancer decreased (from 24.5%, 14.1%, and 3.6% to 22.8%, 9.0%, and 2.6%, respectively), but the incidence of lung cancer, breast cancer, and rectal carcinoma increased from 7.3%, 4.7%, and 1.7% to 12.8%, 6.6%, and 2.4%, respectively. Lung and breast cancer mortality tended to increase, but mortality from stomach cancer and cervical carcinoma showed a tendency to decrease. (2 refs)

78-2984 **Kinetic Models of C3H Mouse Mammary Tumor Growth: Implications Regarding Tumor Cell Loss.** (Eng) Roti Roti, J. L. (Dept. Radiology, Univ. Utah, Salt Lake City, UT, 84132); Bohling, V.; Dethlefsen, L. A. *Cell Tissue Kinet* 11(1): 1-21; 1978.

Three models of tumor cell loss are described. Each model is based on a different cell-loss mechanism, and equations for the cell-cycle, cell-frequency distribution, the growth of proliferating and nonproliferating cell populations, the growth fraction, and the relative rate of volumetric growth are derived. The pulse labeling index, the mitotic index, and the labeling index as a function of time after single or multiple ^{3}H-thymidine (^{3}H-TdR) injections are simulated for each model. All three models have the same mathematical form for the volumetric growth rate. The percent labeled mitosis (PLM) curves predicted by each model for the two mammary tumor lines studied (S102F and Slow) were not appreciably different. The predicted initial labeling index and mitotic index may differ significantly among the models depending on the tumor line. The most striking difference among the models was in the predictions regarding the labeling index as a function of time after a single or a series of ^{3}H-TdR injections. (21 refs)

78-2985 **Model for the Incidence of Embryonal Cancers: Application to Retinoblastoma.** (Eng) Hethcote, H. W. (Dept. Mathematics, Univ. Iowa, Iowa City, IA, 52242); Knudson, A. G. *Proc Natl Acad Sci USA* 75(5): 2453-2457; 1978.

A mathematical model for embryonal cancer incidence was developed that relates age-specific incidence data explicitly to the number of embryonal cell divisions and to rates of somatic mutation per cell division. The Poisson distribution is used to relate incidence data to cellular events. This generalized two-mutation model, which can be used for hereditary and nonhereditary cases, fits well to age-specific incidence data for retinoblastoma. (12 refs)

78-2986 **Growth Fraction as the Major Determinant of Multicellular Tumor Spheroid Growth Rates.** (Eng) Yuhas, J. M. (Cancer Res. and Treatment Center, Univ. New Mexico, 900 Camino de Salud, N.E., Albuquerque, NM, 87131); Li, A. P. *Cancer Res* 38(6): 1528-1532; 1978.

Multicellular tumor spheroids (MTS) from seven murine solid tumor lines were studied to determine the range of their growth rates and the role of the fraction of cells in cycle in these determinations. Growth rates ranged from a low of 19 μm/day to a max of 106 μm/day. This was a far wider range of growth rates than the range observed when the cells were grown as monolayers. A ^{125}I-iodouridine deoxyribose incorporation assay indicated that the cells within the MTS that are in cycle double at a slower rate than they do in monolayers and that the depth of the dividing shell ranges from <20 to >100 μm. The depth of the dividing shell or growth fraction was highly correlated with the MTS growth rate. It is concluded that the major factor that determines the wide range of MTS growth rates is the fraction of cells that are in cycle. (10 refs)

-2987 **A Transitional Cell Carcinoma Cell Line.** (Eng) Moore, G. E. (Dept. Surgery, Denver General osp., W. 8th Ave. and Cherokee St., Denver, CO, 80204); organ, R. T.; Quinn, L. A.; Woods, L. K. *In Vitro* 14(3): 1-306; 1978.

e establishment of a cell line, COLO 232, from a grade 3 ansitional cell carcinoma of the urinary bladder in a -yr-old Caucasian man is reported. In culture, COLO 232 d a doubling time of 48 hr and retained distinct uroepitheli- phenotypic traits. Electron microscopic examination re- aled no viruslike particles. The line also produced both car- oembryonic antigen and ACTH. COLO 232 had a modal romosome number of 58, and it retained the X and Y romosomes. Ten marker chromosomes were identified; five ditional abnormal chromosomes of unknown origin were casionally observed. Injection of culture cells into irradiat- C3H/HeJ mice resulted in tumors at the inoculation site at were morphologically similar to a differentiated bladder rcinoma. The tumor grew in soft agar with a 34% efficien- . (23 refs)

-2989 **Ganglioside and Morphological Changes in Mouse Embryo Cells with Time.** (Eng) Langen- ch, R. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical nter, Omaha, NB, 68105); Malick, L.; Kennedy, S. *Cancer tt* 4(1): 13-19; 1978.

e simultaneous glycolipid, growth, and morphological anges in C3H/10T1/2CL8 cells maintained over a 4-yr riod are reported. During this period, the saturation densi- of the cells increased threefold while the cells were passed nine times and intermittently frozen in liquid nitrogen r approx 3.5 yr. Incorporation of glucosamine-labeled gan- osides into GM_3 (N-acetylneuraminylgalactosylglu- sylceramide) increased about twofold in higher ssage cells and about threefold in MCA-TCL15, a oned chemical transformant from low-passage C3H/ T1/2CL8 cells. The complex ganglioside GD_1a, ich is postulated to function in the density-dependent gulation of cell growth, decreased with passage in the C3H cells; no detectable changes in the ganglioside composition of the MCA cells were observed during 3.5 yr. High-passage C3H cells were fusiform in shape, less flattened, and they exhibited a greater propensity for growing over one another than did low-passage cells. However, they did not exhibit the random growth and aberrant morphology of the MCA cells. The data suggest that there is a relationship among ganglioside composition, cellular morphology, and regulation of cell growth. (27 refs)

78-2990 **Altered Growth Properties of Chinese Hamster Cells Exposed to 1-Methylguanine and 7-Methylguanine.** (Eng) Trewyn, R. W. (Dept. Biochemistry, Univ. Colorado Medical Center, Denver, CO 80262); Kerr, S. J. *Cancer Res* 38(8): 2285-2289; 1978.

Primary Chinese hamster embryo cell cultures generally yield cell lines with a finite lifetime in culture. However, when early-passage cells were exposed chronically to either of two normal degradation products of transfer RNA (tRNA), 1-methylguanine or 7-methylguanine, they were converted to continuous lines with altered growth characteristics and morphology. The continuous cell lines have saturation densities two- to tenfold higher than did finite control cultures, and some have the ability to grow in soft agar. Certain cultures have the general appearance of fibroblasts, but others are more epitheliallike. Quantitative and qualitative alterations in tRNA methyltransferases are early markers for neoplastic transformation in vivo and in vitro. The activity of these enzymes in the continuous lines is elevated compared with that of finite Chinese hamster cells. Neoplastic transformation has been demonstrated for a 1-methylguanine-derived line, and both 1-methylguanine- and 7-methylguanine-treated cell lines exhibit characteristics similar to those of Chinese hamster cells transformed with benzo(a)pyrene and simian virus 40. (24 refs)

78-2991 **Regional Differences in the Incidence and Growth of Mouse Tumors Following Intradermal or Subcutaneous Inoculation.** (Eng) Auerbach, R. (Dept. Zoology, Univ. Wisconsin, Madison, WI, 53706); Morrissey, L. W.; Sidky, Y. A. *Cancer Res* 38(6): 1739-1744; 1978.

The effect of a sc or id inoculation site on the growth of various tumor types (mastocytomas, teratomas, sarcomas, lymphomas, and adenocarcinomas) was investigated in several mouse strains, including athymic or irradiated hosts. With sc and id inoculation, all tumor types, and all strains, tumor cells injected into more cranial regions of the lateral trunk showed greater tumor growth and development than similar cells injected more caudally. At low tumor doses, the incidence anteriorly was double that found posteriorly, and tumors became detectable more rapidly anteriorly; at higher cell doses, the anterior:posterior ratio of tumor wt was 4:1. These findings were not influenced by the sex of the host, the immunogenicity of the tumor, or the immunological competence of the tumor recipient. These findings suggest that "natural variability" in tumor growth could be the result of an experimental protocol and that the regional differences in tumor growth could have an important effect on chemotherapeutic and immunotherapeutic treatment. Studies of innervation, the relationship of specific nerves, and differences in neural connections in the region of a developing tumor may help to explain the present findings. (14 refs)

78-2992 **Successful Transplantation of Human Benign Breast Tumors into the Athymic Nude Mouse and Demonstration of Enhanced DNA Synthesis by Human Placental Lactogen.** (Eng) McManus, M. J. (Dept. Anatomy, Michigan State Univ., East Lansing, MI, 48824); Dombroske, S. E.; Pienkowski, M. M.; Anderson, T. J.; Mann, L. C.; Schuster, J. S.; Vollwiler, L. L.; Welsch, C. W. *Cancer Res* 38(8): 2343-2349; 1978.

Each of 10 biopsy specimens of benign human breast tumors was cut into slices (30 slices/specimen) and transplanted sc into 3 female athymic nude mice (30 mice, 10 grafts/mouse). Of the 3 mice in each of the 10 triads, 2 mice were intact and 1 mouse was ovariectomized 30 days before transplantation. Ten days after transplantation, the following sc injections were administered twice daily for 20 days: 0.9% NaCl soln to one intact and one ovariectomized mouse and 0.5 mg of human placental lactogen (HPL) in 0.9% NaCl solution to one intact mouse of each triad. On the 20th day of injections, each mouse received an ip injection of ^{3}H-thymidine and was sacrificed 1 hr later. Grafts were removed and processed for histological and autoradiographical analyses. Evaluation of DNA synthesis was obtained by counting the total number of ^{3}H-thymidine-labeled epithelial cells in six sections from each graft. All ten biopsy specimens, regardless of host hormonal treatment, were accepted and maintained by these mice. The grafts retained their original morphology. The ductal epithelium of these grafts synthesized DNA, an activity that was significantly increased by HPL. Ovariectomy did not significantly influence the mean DNA incorporation of ^{3}H-thymidine. These results indicate that HPL is a direct stimulant of DNA synthesis of the ductal epithelium of benign human breast tumors. In addition, the athymic nude mouse appears to be a promising model for the in vivo study of factors influencing the development and growth of the human breast. (24 refs)

78-2993 **Cell Population Kinetics of Fast- and Slow-Growing Transplantable Tumors Derived from Spontaneous Mammary Tumors of the DBA/2 Ha-DD Mouse.** (Eng) Pavelic, Z. P. (Dept. Experimental Therapeutics, Roswell Park Memorial Inst., New York State Dep
Health, Buffalo, NY, 14263); Porter, C. W.; Allen, L. M
Mihich, E. *Cancer Res* 38(6): 1533-1538; 1978.

The proliferation kinetics of a fast-growing spontaneo
mouse mammary tumor subline (SMT-F) and a slow-growi
spontaneous mouse mammary tumor subline (SMT-S) tum
were determined autoradiographically at two stages of tum
growth to see if differences in the growth fraction or in c
mitotic cycle times were responsible for differences in tum
growth rate. The length of the cell cycle and the growth fra
tion for SMT-F were 11.2 hr and 0.85, respectively, on d
14, and 12.1 hr and 0.78 on day 28. For SMT-S, the
parameters were 15.6 and 0.50 on day 14, and 16
hr and 0.45 on day 28. On days 14 and 28, the mito
index was 1.3% and 1.0%, respectively, for SMT
and 2.2% and 1.9% for SMT-F. The cell loss rate, c
loss factor, and cell loss were significantly higher f
SMT-F than for SMT-S. It is concluded that t
difference in the growth rates for these two tum
lines is the result of a slight prolongation of the length of t
cell cycle and a reduction in the growth fraction of SMT-
(13 refs)

R. W. (Sidney Farber Cancer Inst., Boston, MA, 02115); Sa
ford, K. K.; Frankel, F. R. *Cell* 13(4): 629-642; 1978.

Pairs of nonneoplastic and spontaneously transformed ne
plastic cells were derived from rat, mouse, and hams
embryos. The neoplastic cells of each pair had po
ly spread cellular morphology, grew in agarose in vit
and produced invasive sarcomas in vivo; the nonn

astic cells exhibited none of these properties. The stribution of microtubules and microfilament bundles tress fibers or actin cables) was examined in five ch paired lines and in 3T3 and simian virus 40-trans- rmed 3T3 cells by indirect immunofluorescent micro- opy of fixed cells treated with rabbit antibody ainst bovine brain tubulin or guinea pig smooth muscle tin. Actin cables in all the neoplastic cells were thinner and arser than those in the paired nonneoplastic cells. These fferences were also observed in living cells with polarization icroscopy. In contrast, microtubules were similar in neo- astic and nonneoplastic cells, both in areas of thin peripher- lamellar cytoplasm that allowed a clear visualization of ie, curving microtubules and in regions of thick, central idoplasm that obscured individual microtubules. The main orphological difference between neoplastic and nonneo- astic cells was the relative amount of lamellar cytoplasm endoplasm, rather than the appearance of microtubules in ther region. Thus, the distinctive growth properties and re- acted cellular morphology of neoplastic cells did not corre- te with decreased or disorganized microtubules, but with in and sparse actin cables. 3-2999 Altered Levels of Cyclic Nucleotides, Cyclic **AMP Phosphodiesterase and Adenylyl Cyclase ctivities in Normal, Dysplastic and Neoplastic Human lammary Tissue.** (Eng) Kung, W. (Hormone Lab. and Ex- rimental Endocrinology, Dept. Gynecology, Univ. Clinic ledical Sch., 4004 Basel, Switzerland); Bechtel, E.; Geyer, ; Salokangas, A.; Preisz, J.; Huber, P.; Torhorst, J.; Jung- ann, R. A.; Talmadge, K.; Eppenberger, U. *FEBS Lett* !(1): 102-106; 1977.

yclic AMP (cAMP), cyclic guanosine monophosphate 3MP), cAMP phosphodiesterase, and adenyl cyclase levels were investigated in normal, dysplastic, and neoplastic human breast tissue obtained during mastectomy, biospy, or plastic surgery. cAMP levels were significantly higher in primary carcinoma (CA) tissue than in normal or slightly dysplastic tissue. cAMP concentrations in fibroadenomas were slightly lower than those in CAs. cAMP levels were significantly elevated in CA tissue compared to normal and simple dysplastic tissue. Phosphodiesterase concentrations were measured at 6 x 10^{-8} and 1 x 10^{-6} M cAMP. At both concentrations, phosphodiesterase activities were significantly increased in CA as opposed to normal tissue. At the lower substrate concentration, phosphodiesterase activity was significantly higher in proliferative dysplasia, CA, and fibroadenoma tissue. Adenyl cyclase activities were significantly elevated in simple proliferative dysplasia and CA tissue compared to normal tissue. When relative cellular levels were considered, there were markedly lower levels of adenyl cyclase activity in CA and lower cAMP and cGMP levels in CA and proliferative dysplasia tissue compared to normal tissue. Similarly, relative cellular phosphodiesterase activities were lower in CA and proliferative dysplasia tissue than in normal tissue. (8 refs)

78-3000 **Inhibition of Ovariectomy-induced Rat Mammary Tumor Regression by a Mammosomatotropic Tumor.** (Eng) Diamond, E. J. (Res. Inst., Hosp. Joint Diseases, Mount Sinai Sch. Medicine, New York, NY, 10035); Khan, S.; Koprak, S.; Hollander, V. P. *Cancer Res* 38(8): 2239-2245; 1978.

The growth of the transplantable rat mammary carcinoma MTW9 is stimulated by elevated serum prolactin concentrations. MTW9 grown in rats with high serum (PL) produced by coimplantation of a mammosomatotropic tumor, MtTW10 (MTW9-MtT), does not regress after ovariectomy (OVEX). MTW9 grown in rats with high serum PL produced by daily administration of perphenazine (MTW9-P) does regress after ovariectomy whether perphenazine treatment is continued (MTW9-P) or not (MTW9-PD). Experiments were designed to determine whether some hormonal abnormality in MtTW10-bearing rats might prevent OVEX-induced mammary tumor regression. The hormone environment of hosts bearing MtTW10 was simulated in rats bearing MTW9-PD. High doses of ACTH, growth hormone (GH) 17-hydroxyprogesterone caproate, and PL failed to inhibit OVEX-induced regression. A high-dose mixture of PL, ACTH, and GH administered to a limited number of rats produced extreme mammary stimulation, but it also failed to inhibit tumor regression. Implantation of MtTW10 into animals bearing MTW9-PD prevented OVEX-induced regression of mammary tumor. These data are consistent with the suggestion that OVEX-induced regression is inhibited by the secretion of a factor other than PL, GH, ACTH, although some combination of hormones present in MtTW10-bearing rats cannot be excluded. Subject Index

bnormalities
- 1,2-Benzisothiazolin-3-one, 1,1-Dioxide-, Sodium Salt
  - Histological Study, Perinatal Rat Eye, 78-2681
- Cyclohexanesulfamic Acid, Monosodium Salt
  - Histological Study, Perinatal Rat Eye, 78-2681
- Radiation, Ionizing
  - Ovary, Mouse, 78-2752
- 4,4′-Stilbenediol, α,α′-Diethyl-
  - Genital Tract, 78-2509
  - Genital Tract, Monkey, 78-2511
- 1*H*-1,2,4-Triazole-3-carboxamide, 1-β-*D*-Ribofuranosyl-
  - Adenine, 78-2665
  - Embryo, Hamster, 78-2665
  - Guanine, 78-2665

cetamide, *N*-(Acetyloxy)-*N*-fluoren-2-yl-
- DNA
  - Mutagenic Activity, 78-2658, 78-2659
- Genetics
  - Mutagenic Activity, 78-2660
- Urogenital Neoplasms
  - Pregn-4-ene-3,20-dione, 17-(Acetyloxy)-6α-methyl- 78-2655

cetamide, *N*-Fluoren-2-yl-
- Bladder Neoplasms
  - Dietary Fats, 78-2654
  - Dietary Proteins, 78-2654
- DNA
  - Alkaline Elution Assay, 78-2718
  - Mutagenic Activity, 78-2659
- Hepatoma
  - Galactosyltransferases, 78-2651
  - Gangliosides, 78-2653
  - Glutamyl Transpeptidase, 78-2712
  - Glycolipids, 78-2651
  - Precancerous Conditions, 78-2653, 78-2712
  - Sialic Acid, 78-2653
- Liver Neoplasms
  - Dietary Fats, 78-2654
  - Dietary Proteins, 78-2654
- Metabolism, Activation
  - Isolation and Characterization, Parenchymal Cells 78-2525
- Microsomes, Liver
  - Ames Test, 78-2652
- Mitochondria, Liver
  - Ames Test, 78-2652
- Nicotinamide, *N*-Methyl-
  - Metabolism, Liver, 78-2650
- Oxidoreductases
  - Liver, Rat, 78-2650
- Precancerous Conditions
  - Metabolism, Liver, 78-2652
- 4-Pyridone-5-carboxamide, 1-Methyl-
  - Oxidoreductases, 78-2650
- Selenium
  - Mutagenic Activity, 78-2657
  - *Salmonella typhimurium*, 78-2657
- Thymidine Kinase
  - Mutagenic Activity, 78-2649

cetamide, *N*-Fluoren-4-yl-
- Thymidine Kinase
  - Mutagenic Activity, 78-2649

Acetamide, 2-Iodo-
- Stomach Neoplasms
  - Guanidine, 1-Methyl-3-nitro-1-nitroso-, 78-2571

Acetic Acid, Chloro-
- Ethylene, 1,1-Dichloro-
  - Carcinogenic Metabolite, 78-2635
  - Urinary Metabolite, Rat, 78-2636

Acetic Acid, Ethyl Ester
- Cell Transformation, Neoplastic
  - Embryo Cells, Hamster, 78-2692
  - Tars, Tobacco, 78-2692
- Intestinal Neoplasms
  - Carcinogenic Metabolite, 78-2549

Acetic Acid, (Ethylenebis(oxyethylenenitrilo))tetra-
- Virus, Polyoma
  - DNA-Protein Complex, 78-2829

Acetic Acid, Mercapto-
- Ethylene, 1,1-Dichloro-
  - Urinary Metabolite, Rat, 78-2636

Acetic Acid, Thiodi-
- Ethylene, 1,1-Dichloro-
  - Urinary Metabolite, Rat, 78-2636

Acetic Acid, Trichloro-
- Ethylene, 1,1-Dichloro-
  - Metabolism, Rat, 78-2635
- Ethylene, Tetrachloro-
  - Urine, 78-2638

Acetohydroxamic Acid, *N*-Fluoren-2-yl-
- DNA
  - Alkaline Elution Assay, 78-2718
- Genetics
  - Mutagenic Activity, 78-2660
- Mammary Neoplasms, Experimental
  - 5α-Androstan-3-one, 17β-Hydroxy-, 78-2656
  - Dexamethasone, 78-2656
  - Estradiol, 78-2656
  - Progesterone, 78-2656
  - Receptors, Hormone, 78-2656
- Microsomes, Liver
  - Ames Test, 78-2652
- Mitochondria, Liver
  - Ames Test, 78-2652
- Selenium
  - Mutagenic Activity, 78-2657
  - *Salmonella typhimurium*, 78-2657

Aclacinomycin A
- *Salmonella typhimurium*
  - Mutagenic Activity, 78-2532

Aclacinomycin A, *N*-Demethyl-
- *Salmonella typhimurium*
  - Mutagenic Activity, 78-2532

Acridine, 9-Amino-
- Nucleotides
  - Binding, 78-2538
  - Proton Shifts, 78-2538

Acridine, 3,6-Diamino-
- DNA Repair
  - Germ Cells, 78-2539

Acridine, 3,6-Diamino- (cont'd)
- Intestinal Mucosa
  - Activation, Mutagen, 78-2486

Acrylonitrile
- *Salmonella typhimurium*
  - Mutagenic Activity, Review, 78-2423

Actin
- Cell Transformation, Neoplastic
  - Embryo, Rat, 78-2996
  - Ultrastrucutral Study, 78-2996
- Lymphocytes
  - Immunoglobulins, Surface, 78-2937
- Plasmacytoma
  - Binding, 78-2937
- Virus, SV40
  - Cell Transformation, Neoplastic, 78-2996

Actinomycin D
- *Neurospora crassa*
  - Mutagenic Activity, 78-2673
- Virus, Murine Leukemia
  - DNA Replication, 78-2786
  - Reverse Transcriptase, 78-2786

Adenine
- 1*H*-1,2,4-Triazole-3-carboxamide, 1-β-*D*-Ribofuranosyl-
  - Abnormalities, 78-2665
  - Fetal Death, 78-2665

Adenocarcinoma
- Cecal Neoplasms
  - Daunomycin Hydrochloride, 78-2536
- Cervix Neoplasms
  - Hydatidiform Mole, 78-2962
- Colonic Neoplasms
  - Daunomycin Hydrochloride, 78-2536
  - Hydrazine, 1,2-Dimethyl-, 78-2671, 78-2672
  - Ultrastructural Study, Mouse, Rat, 78-2953
- Ethane, 1,1-Dichloro-
  - Carcinogenic Activity, Rat, 78-2628
- Intestinal Neoplasms
  - Panfuran-S, 78-2726
- Kidney Neoplasms
  - 1,3-Butadiene, Hexachloro-, 78-2645
  - 2-Imidazolidinone, 1-(5-Nitro-2-thiazolyl)-, 78-2725
- Lung Neoplasms
  - Asbestos, 78-2504
  - Benzilic Acid, 4,4'-Dichloro-, Ethyl Ester, 78-2595
  - 2-Propanol, 1,1'-Iminodi-*N*-nitroso-, 78-2698
- Mammary Neoplasms, Experimental
  - Cell Division, 78-2993
  - Neoplasm Transplantation, 78-2991
  - Ultrastructural Study, Mouse, Rat, 78-2953
- Respiratory Tract Neoplasms
  - Benzo(a)pyrene, 78-2495
- Salivary Gland Neoplasms
  - Benz(a)anthracene, 7,12-Dimethyl-, 78-2611
- Stomach Neoplasms
  - Guanidine, 1-Methyl-3-nitro-1-nitroso-, 78-2562 78-2563
- Tracheal Neoplasms
  - Urea, Methyl Nitroso-, 78-2579
- Uterine Neoplasms
  - Estrogenic Substances, Conjugated, 78-2425
  - 4,4'-Stilbenediol, α,α'-Diethyl-, 78-2514

Adenocarcinoma, Papillary
- Intestinal Neoplasms

Adenocarcinoma, Papillary (cont'd)
  - Panfuran-S, 78-2726

Adenofibroma
- Breast Neoplasms
  - Adenosine Cyclic 3',5' Monophosphate, 78-2999
  - Adenyl Cyclase, 78-2999
  - Carcinoma In Situ, 78-2949
  - Guanosine Cyclic 3',5' Monophosphate, 78-2999
  - Phosphodiesterases, 78-2999
  - Transplantation, Heterologous, 78-2992

Adenoma
- Bronchial Neoplasms
  - Ethylene, Chloro-, 78-2632
  - Ethylene, 1,1-Dichloro-, 78-2632
- Colonic Neoplasms
  - Bile Acids and Salts, 78-2970
- DNA Replication
  - Caffeine, 78-2676
  - 2-Imidazolidinone, 1-(5-Nitro-2-thiazolyl)-, 78-2725
- Kidney Neoplasms
  - 1,3-Butadiene, Hexachloro-, 78-2645
- Liver Neoplasms
  - Contraceptives, Oral, 78-2460, 78-2519
- Lung Neoplasms
  - 1-Butanone, 4-(*N*-Methyl-*N*-nitrosamino)-1-(3-pyridyl)-, 78-2694
  - Butyraldehyde, 4-(*N*-Methyl-*N*-nitrosamino)-4-(3-pyridyl)-, 78-2694
  - Carbamic Acid, Ethyl Ester, 78-2676
  - Nicotine, 1'-Nitroso-1'demethyl-, 78-2694
  - 2-Propanol, 1,1'-Iminodi-*N*-nitroso-, 78-2698
- Rectal Neoplasms
  - Bile Acids and Salts, 78-2970

Adenosine Cyclic 3',5' Monophosphate
- Breast
  - Precancerous Conditions, 78-2999
- Breast Neoplasms
  - Adenofibroma, 78-2999
  - Carcinoma, 78-2999

Adenyl Cyclase
- Breast
  - Precancerous Conditions, 78-2999
- Breast Neoplasms
  - Adenofibroma, 78-2999
  - Carcinoma, 78-2999
- Ferrate, Pentacyanonitrosyl-, Disodium
  - Adrenal Cortex, 78-2565
- Guanidine, 1-Methyl-3-nitro-1-nitroso-
  - Adrenal Cortex, 78-2565

Adrenal Cortex
- Ferrate, Pentacyanonitrosyl-, Disodium
  - Adenyl Cyclase, 78-2565
  - Guanyl Cyclase, 78-2565
- Guanidine, 1-Methyl-3-nitro-1-nitroso-
  - Adenyl Cyclase, 78-2565
  - Guanyl Cyclase, 78-2565

Adrenal Gland Neoplasms
- Brain Neoplasms
  - Genetics, Review, 78-2450
- Endrin
  - Dose-Response Study, 78-2602
- Neoplasms, Multiple Primary
  - Genetics, Review, 78-2450

Adrenal Glands
  Aryl Hydrocarbon Hydroxylases
    Fetus, 78-2705

Adriamycin
  DNA Repair
    Germ Cells, 78-2539
  Guanidine, 1-Propyl-3-nitro-1-nitroso-
    Guanyl Cyclase, 78-2561
  Hydrazine
    Guanyl Cyclase, 78-2561

Aflatoxicol
  Aflatoxin B1
    Carcinogenic Metabolite, Plasma, 78-2523
    Toxicity, 78-2523

Aflatoxin B1
  Aflatoxicol
    Carcinogenic Metabolite, Plasma, 78-2523
    Toxicity, 78-2523
  Aflatoxin D1
    Ammonium, 78-2521
  Aflatoxin M1
    Carcinogenic Metabolite, Urine, 78-2523
  Ammonium
    Metabolism, 78-2521
  Cytochrome P-450
    Mutagenic Activity, 78-2704
  DNA
    Alkaline Elution Assay, 78-2718
  DNA Repair
    Carcinogenic Potential, Review, 78-2436
    Mutagenic Activity, Review, 78-2434
  Enzyme Activation
    Carcinogenic Metabolite, 78-2642
  Escherichia coli
    Mutagenic Activity, Review, 78-2434
  Formamide, *N,N*-Dimethyl-
    Carcinogenic Potential, Gerbil, 78-2522
    Skin Absorption, 78-2522
  Genetics
    Mutagenic Activity, 78-2660
  Hepatoma
    Alpha Fetoproteins, 78-2596
  Isocitrate Dehydrogenase
    Serum Albumin, Bovine, 78-2524
  Liver
    Carcinogenic Potential, Gerbil, 78-2522
  Liver Neoplasms
    Food Contamination, 78-2435
  Metabolism
    Species Difference, 78-2523
  Metabolism, Activation
    Isolation and Characterization, Parenchymal Cells 78-2525
  Propane, 1,2-Epoxy-3,3,3-trichloro-
    Carcinogenic Metabolite, 78-2642
  Serum Albumin, Bovine
    Hepatotoxicity, 78-2524
    Immunization, 78-2524
  Skin Absorption
    Carcinogenic Potential, Gerbil, 78-2522
  Toxicity
    Tissue/Plasma Transfer Rates, 78-2523

Aflatoxin B1 2,3-Oxide
  Propane, 1,2-Epoxy-3,3,3-trichloro-
    Enzyme Activation, 78-2642

Aflatoxin D1
  Aflatoxin B1
    Ammonium, 78-2521

Aflatoxin M1
  Aflatoxin B1
    Carcinogenic Metabolite, Urine, 78-2523

Agmatine
  see Guanidine, (4-Aminobutyl)-

Air Pollution
  Asbestos
    Carcinogenic Activity, Review, 78-2458
    Epidemiology, Review, 78-2458
  Benzene
    Carcinogenic Activity, Review, 78-2418
  Ether, Bis(chloromethyl)-
    Quantitation Method, 78-2646

Alexidine
  Salmonella typhimurium
    Mutagenic Activity, 78-2543

Alkaline Phosphatase
  Virus, Herpes Simplex 2
    Cell Transformation, Neoplastic, 78-2861

Alkylating Agents
  Carcinogen, Chemical
    Co-carcinogenic Activity, 78-2748
  DNA
    Dose-Response Study, 78-2403
  DNA Repair
    Germ Cells, 78-2539

Allyl Chloride
  see Propene, 3-Chloro-

Allyl Cyanide
  see 3-Butenenitrile

Alpha Fetoproteins
  Hepatoma
    Aflatoxin B1, 78-2596
    Aniline, *N,N*-Dimethyl-*p*-phenylazo-, 78-2596
    Benzenamine, *N,N*-Dimethyl-4-((3-methylphenyl)azo)-, 78-2596
    Serum Levels, 78-2596
  Kidney Neoplasms
    Cell Membrane, 78-2719

Alpha Particles
  Cell Transformation, Neoplastic
    Cell Density, 78-2757

Ames Test
  Acetamide, *N*-Fluoren-2-yl
    Microsomes, Liver, 78-2652
    Mitochondria, Liver, 78-2652
  Acetohydroxamic Acid, *N*-Fluoren-2-yl-
    Microsomes, Liver, 78-2652
    Mitochondria, Liver, 78-2652
  Carcinogen, Environmental
    Review, 78-2406
  Ethane, 1,2-Dichloro-
    Review, 78-2406

Amino Acids
  Methanesulfonic Acid, Methyl Ester
    Mutagenic Activity, Alkylating Agents, 78-2679
  Virus, Adeno 2
    Viral Proteins, 78-2879, 78-2885

Amino Acids (cont'd)
- Virus, Avian Myeloblastosis
  - Peptides, 78-2766
- Virus, Rauscher Murine Leukemia
  - Viral Proteins, 78-2818
- Virus, SV40
  - Cell Transformation, Neoplastic, 78-2853

3-Amino-1*H*-1,2,4-triazole
- *see* *s*-Triazole, 3-Amino-

***o*-Aminoazotoluene**
- *see* *o*-Toluidine, 4-(*o*-Tolylazo)-

4-Aminobiphenol
- *see* Biphenyldiol, 4-Amino-

Ammonium
- Aflatoxin B1
  - Aflatoxin D1, 78-2521
  - Metabolism, 78-2521

Androgens
- Hepatoma
  - Epidemiology, Review, 78-2460
- Liver Neoplasms
  - Epidemiology, Review, 78-2460

Androst-5-ene-3β,17β-diol
- Mammary Neoplasms, Experimental
  - Benz(a)anthracene, 7,12-Dimethyl-, 78-2616
  - Receptors, Hormone, 78-2616

5α-Androstan-3-one, 17β-Hydroxy-
- Mammary Neoplasms, Experimental
  - Acetohydroxamic Acid, *N*-Fluoren-2-yl-, 78-2656

Androsterone
- Breast Neoplasms
  - Genetics, 78-2951

Anemia
- Erythropoietin
  - Biological Activity, Review, 78-2448
- Histocompatibility Antigens
  - Epidemiology, Mouse, 78-2919
- Neoplasms
  - Erythropoietin, 78-2448

Anemia, Aplastic
- Benzene
  - Epidemiology, Review, 78-2418
- Genetics
  - Case Report, 78-2947
- Leukemia, Lymphoblastic
  - Genetics, 78-2947

Anemia, Pernicious
- Nitrous Acid
  - Bacteria, 78-2696
  - Precancerous Conditions, 78-2696
- Stomach Neoplasms
  - Precancerous Conditions, 78-2696

Angiosarcoma
- Bone Neoplasms
  - *o*-Toluidine, 4-(*o*-Tolylazo)-, 78-2589
- Ethane, 1,2-Dibromo-
  - Disulfide, Bis(diethylthiocarbamoyl)-, 78-2623
- Ethane, 1,1-Dichloro-
  - Carcinogenic Activity, Rat, 78-2628
- Ethylene, Chloro-
  - Epidemiology, Review, 78-2460

Angiosarcoma (cont'd)
- Ethylene, 1,1-Dichloro-
  - Dose-Response Study, Mouse, Rat, 78-2632
- Lasiocarpine
  - Carcinogenic Activity, Rat, 78-2548
  - Neoplasm Metastasis, 78-2548

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by the Franklin Institute Press^{SM}.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 15, consisting of 12 monthly issues and a cumulative index is $75.00, Domestic and $90.00, Foreign. Check should be made payable to The Franklin Institute Press.

Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 15, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations.*

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)
ACTH	adrenocorticotropic hormone
ADP	adenosine diphosphate
AMP	adenosine monophosphate
ATP	adenosine triphosphate
approx	approximately
av	average
BCG	bacillus Calmette-Guerin
bid	twice daily
C	degree(s) centigrade
cal	calorie(s)
kcal	kilocalorie(s)
cc	cubic centimeter(s)
Ci	curie(s)
mCi	millicurie(s)
μCi	microcurie(s)
cm	centimeter(s)
CNS	central nervous system
cpm	counts per minute
DNA	deoxyribonucleic acid
ED_{50}	median effective dose
EDTA	ethylenediamine tetraacetic acid
g	gram(s)
kg	kilogram(s)
mg	milligram(s)
μg	microgram(s)
Hb	hemoglobin
hr	hour(s)
ia	intra-arterial
id	intradermal
IgA	Immunoglobulin A
IgB	Immunoglobulin B

REVIEW

78-3001 **Health Effects of Exposure to Low Levels of Regulated Air Pollutants. A Critical Review.** (Eng) Ferris, B. G. (Harvard Sch. Public Health, 665 Huntington Ave., Boston, MA, 02115). *J Air Pollut Control Assoc* 28(5): 482-497; 1978.

The health effects of various air pollutants are discussed and the means of control are reviewed. The present primary standards for particulate matter, sulfur oxides, carbon monoxide, nitrogen dioxide, photochemical oxidants, and hydrocarbons seem adequate to protect public health. There are insufficient and inadequate data to establish a standard for sulfur oxides at this time but the evidence to date does not seem to support the contention that the concentration of sulfur oxides in suburban atmospheres in the US plays a significant role in the production of lung cancer. (142 refs)

78-3002 **In Vitro Chemical Carcinogenesis and Co-Carcinogenesis in Human Cells Initiated by Hydrazine & Polynuclear Components of Jet Fuel (Meeting Abstract).** (Eng) Milo, G. E. (Ohio State Univ., Sch. Veterinary Medicine, Columbus, OH, 43210). *Sci Tech Aerospace Rep* 16(12): P-30; 1978. (no refs)

78-3003 **Analytical Problems in Meeting WHO Limits for PAHs in Water.** (Eng) Crathorne, B. (Water Res. Centre, Medmenham Lab., P.O. Box 16, Henley Road, Medmenham, Marlow, Buckinghamshire, SL7 2HD, England). *Proc Analyt Div Chem Soc* 15(5): 155-158; 1978.

Problems involved in analyzing drinking water for polycyclic aromatic hydrocarbons (PAH) in order to meet the World Health Organization's standard of a max 200 nanograms/liter for total PAH are discussed. Total PAH refers to the sum of the levels of six specified PAH. The choice of these PAH makes it difficult to apply alternative analytical techniques to improve the accuracy of the data. (6 refs)

78-3004 **Analytical Aspects of Polycyclic Aromatic Hydrocarbons in Food.** (Eng) Knowles, M. E. (Ministry Agriculture, Fisheries and Food, 65 Romney St., London SW1P 3RD, England). *Proc Analyt Div Chem Soc* 15(5): 153-155; 1978.

Two major analytical methods for identifying polycyclic aromatic hydrocarbons in food are reviewed. The first is the collective or total method, which does not involve the separation or identification of individual components. The second consists of various chromatographic systems for separating and identifying selected or total components of the hydrocarbon extract. (no refs)

78-3005 **The Determination of Polycyclic Aromatic Hydrocarbons.** (Eng) Roe, F. J. (4 Kings Road, Wimbledon, London, SW19 8QN, England). *Proc Analyt Div Chem Soc* 15(5): 148-153; 1978.

The carcinogenicity of polycyclic aromatic hydrocarbons is reviewed. The various topics include the historical perspective, results of animal and human epidemiological studies, chemical studies of the mechanism of carcinogenesis and identification of the ultimate carcinogen, and interpretation of cocarcinogenicity studies. (42 refs)

78-3006 **Comments on Extrapolation of Cancer Response from High Dose to Low Dose.** (Eng) Nelson, N. (Inst. Environmental Medicine, New York Univ. Medical Center, 550 First Ave., New York, NY, 10016). *Environ Health Perspect* 22: 93-95; 1978.

In making judgments as to the risk of cancer from low-level exposure to carcinogens, it is generally necessary to base these judgments on high-dose or high-incidence data from laboratory or epidemiological studies. The use of laboratory animal models for estimates of carcinogenic response that are meaningful for humans can be of value in some of the simpler situations, such as those involving high-dose, direct-acting agents (eg, ionizing radiation or alkylating chemicals). However, laboratory data become progressively less reliable as the situations increase in complexity, involving extrapolation from one species to another, agents requiring activation, activation in one organ with production of tumors in another, and coacting enzymes with stimulatory or inhibitory influences. Curves relating cancer response to dose appear to exhibit a quasi-threshold, although closer inspection usually shows them to be lines with a lower slope starting from the origin then moving up exponentially. Numerous dose-response models have also been devised, although these models have restricted practical application since the basic data are rarely available. It appears that at present, the most confident estimations of the quantitative impact of air pollution on human cancer will come from epidemiological data that, in some instances, may be reinforced by data on laboratory animals. (11 refs)

78-3007 **Dose-Effect Relationships in Carcinogenesis and the Matter of Threshold of Carcinogenesis.** (Eng) Jones, H. (Medical Physics and Physiology, Donner Lab., Univ. California, Berkeley, CA, 94720). *Environ Health Perspect* 22: 171-172; 1978.

The relationships between the degree of exposure to a carcinogen and both the risk that neoplasms will occur and the time of their appearance serve as bases for an explanation of the nature of carcinogenesis. A model constructed from quantitative expressions of these relationships implies that neoplasms resulting from a single exposure to a carcinogen should be closely distributed in time, producing a pulse of cases and then being essentially without effect. The stages in the development of cancer appear to be as follows: (1) changes affecting cellular functions are induced by carcinogens and involve alterations of DNA or RNA that are transmissible to daughter cells; (2) interactions occur between clones of altered cells, and these are responsible for the relationship between dose and time of tumor appearance; (3) organ changes produced by these cellular alterations may reach a level at which they cause failure of the tissue-organizing systems that normally prevent the development of neoplasms; (4) the cancer-suppressing mechanism of the entire body appears to fail, allowing extension of a neoplasm to threaten the function of the body as a whole; and (5) uncontrolled growth typical of acute malignancies. (3 refs)

78-3008 Biologic Evidence for the Existence of Thresholds in Chemical Carcinogenesis. (Eng) Falk, H. L. (Office Health Hazard Assessment, Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC, 27709). *Environ Health Perspect* 22: 167-170; 1978.

Aspects of the first phases of carcinogenesis are presented as evidence for the existence of thresholds in this process. Several processes that have no relationship to carcinogenesis, such as absorption by the organism and metabolic change, have great bearing on the concept of thresholds because of their potential capacity to reduce the number of active molecules available for carcinogenesis. Additional variables that influence thresholds are inherent in the reactions between DNA and the chemicals that are effective alkylating agents, and those that affect DNA repair are especially critical. The extent to which DNA damage can be repaired depends on the site of alkylation, and DNA repair of succeeding alkylations is less effective. Since, at least in mice, there are levels of carcinogen exposure that will produce only dormant, initiated cells unless adequate promotion is supplied, a promoter must lower the threshold for the production of observabl tumors. The existence of thresholds in carcinogenesis is als supported by the interactions between carcinogens and structurally related chemicals, which in experimental animals depend on the dose and type of treatment. Thresholds for carcinogenesis may be further influenced by inhibitory processe such as metabolic detoxification and factors such as nutrition intercurrent disease, and exposure to other chemicals. Th fact that a number of carcinogenic molecules in low concentrations are essential constituents of the mammalian systen throughout life without causing cancer is more evidence fo the reality of thresholds in carcinogenesis. (13 refs)

78-3009 **Extrapolation of Carcinogenesis Data.** (Eng Lepkowski, W. (1620 Wainright Drive, Reston VA, 22090). *Environ Health Perspect* 22: 173-181; 1978.

The state of the art of biomedical research, as used to estimat the potential public health consequences of long-term huma exposure to chemical agents in the environment, was discussed at a 1976 conference in Pinehurst, North Carolina Presumptive tests in single cell organisms and mammalia cells can be used to determine whether or not a substance i carcinogenic, and animal tests can be used to quantitativel estimate the risk of carcinogenicity in humans. Problems i making extrapolations from animals to man include those o metabolic variability among and within species and the diversity in susceptibility to cancer among different human subgroups. No one species can serve as a model for the metabolism of all compounds in humans, and science has no progressed to the point of allowing assured species-to-specie extrapolations. A major point of controversy is whether tim or the latency period will nullify the carcinogenicity of chemicals in small doses. Some of the mathematical bases for ris extrapolation include the threshold hypothesis, the single-event hypothesis, and the probit and other hypotheses implying a dose-response curve that is concave upward. I would seem prudent to employ the single-event hypothesi in making risk estimates. Other points made at the conferenc were that the cancer age distribution is dose-independent bu risk is dose-proportional, that different statistical model yield markedly different extrapolations, and that low-dos linearity cannot be ruled out statistically. Thresholds and th contributions of epidemiological data to the problem of extrapolation were also discussed. (no refs)

78-3010 **Structural Analysis as a Means of Predictin Carcinogenic Potential.** (Eng) Ashby, J. (Imperial Chemical Industries Ltd., Central Toxicology Lab. Alderley Park, Cheshire, England). *Br J Cancer* 37(6) 904-923; 1978.

If structural analysis is to be used as a means of predictin carcinogenic potential, attention must be given to whic structural features are associated with carcinogenicity and which structural changes can nullify that association. A full understanding of inter- and intraseries effects will only follow from the consideration of factors such as metabolic transformations, the ultimate carcinogenic form, changes in basicity, acidity partition coefficients, and relative steric effects. Some broad structure-activity comparisons are outlined for the aromatic amines; arylamine carcinogens; 4-nitroquinoline N-oxide and its analogs; the polycyclic aromatic hydrocarbons; nitrosamines, nitrosamides, hydrazines, and azoxyalkyl compounds; alkylating agents; and other miscellaneous groups. For each class, an attempt was made to generate generalized structures associated with carcinogenicity, and the range of molecular changes that could be made to a carcinogen without loss of carcinogenic activity was identified. If structural analysis is to be used as a method of predicting carcinogenicity, certain problems must be recognized; eg, many compounds may be classed as potential carcinogens by virtue of an activation pathway in their metabolism, but only those for which such a pathway is significant in their overall metabolism would prove active. Furthermore, compounds such as saccharin and phenobarbitone, which induce tumors in animals, are not classified as carcinogens on the basis of structural analysis. (179 refs)

78-3011 **Carcinogenicity Testing of Chemical Substances.** (Slo) Slamenova, D. (Ustav experimentalnej onkologie, Slovenska akademie vied, Mlynske Nivy 59, 880 32 Bratislava, Czechoslovakia); Maskova, L.; Budayova, E. *Biologia* 33(3): 233-242; 1978.

Certain microorganisms, such as *Salmonella typhimurium*, *Escherichia coli*, and *Saccharomyces cerevisiae*, are suitable for the carcinogenicity and mutagenicity testing of chemical substances and for study of the metabolic activation of precarcinogens. (22 refs)

78-3012 **Relevance of Short-term Carcinogenicity Tests to the Study of the Carcinogenic Potential of Urban Air.** (Eng) Harnden, D. G. (Dept. Cancer Studies, Univ. Birmingham, England). *Environ Health Perspect* 22: 67-70; 1978.

A variety of short-term tests have been developed to evaluate the potential carcinogenicity of chemical compounds. These tests depend on mutagenicity, stimulation of DNA repair, induction of chromosome damage, and other actions to indicate carcinogenic potential. These assays are rapid and cheap, and some tests can be carried out using human cells. The short-term assays may have advantages in the context of air pollution since they are sensitive down to very low dose levels and can deal with complex mixtures. Combinations of such assays may be of more value than any single test. Their particular value may be a preliminary screening procedure in a tiered testing program. The early warning that such studies could give might help in reducing pollution as soon as possible and serve to prevent human morbidity. (19 refs)

78-3013 **The Value and Significance of Carcinogenic, Mutagenic, and Teratogenic Tests.** (Eng) Brusick, D. J. (Dept. Genetics, Litton Bionetics, Inc., Kensington, MD). *In: Cutaneous Toxicity.* Drill, V.A; Lazar, P.,eds. (New York: Academic Press Inc.) : pp. 189-201; 1978.

The value and reliability of in vivo and in vitro tests for determining the carcinogenicity, mutagenicity, and teratogenicity of a compound are discussed. Studies have found a positive correlation of approx 0.90 between carcinogenicity and mutagenicity and a positive correlation of approx 0.98 between noncarcinogenicity and nonmutagenicity. Reasons for the lack of complete correlation are outlined. The absorption of cutaneously applied substances, their systemic disposition, and the placental/gonadal penetration of these substances are considered. Based on these considerations, a composite test system to screen compounds for carcinogenicity, mutagenicity, and teratogenicity is proposed. The critical feature of this composite series of tests is the use of a T-strain of mice homozygous for several coat color genes. End points that can be detected and quantitated are enumerated. For each compound, the overall cost of the test system would be approx 20,000 dollars, and the test would take only 3-4 mo. (30 refs)

78-3014 **Biological Interactions of N-Nitroso Compounds: A Review.** (Eng) Olajos, E. J. (Inst. Comparative and Human Toxicology, Albany Medical Coll., Union Univ., Albany, NY, 12208). *Ecotoxicol Environ Saf* 1(2): 175-196; 1977.

The chemistry, metabolism, and biological interactions of N-nitroso compounds are reviewed. The possibility that alkylation of proteins and nucleic acids by these compounds is related to their mutagenicity or carcinogenicity is discussed. Genetic and epigenetic mechanisms by which the active forms of chemical mutagens and carcinogens react with informational molecules and proteins are summarized. The usefulness of nitrosamines and nitrosamides in mutagenicity and carcinogenicity studies is stressed. Continued work in this area may lead to an understanding of carcinogenic organotropism, mechanisms of genetically influenced susceptibility to chemically induced cancers, and initial processes involved in carcinogenesis and mutagenesis. (167 refs)

78-3015 **Toxicologic Perspectives of Chemicals Commonly Applied to Skin.** (Eng) Maibach, H. I.

(Dept. Dermatology, Univ. California Sch. Medicine, San Francisco, CA); Marzulli, F. N. *In: Cutaneous Toxicity.* Drill, V. A.; Lazar, P., eds. (New York: Academic Press, Inc.): 277 pp.; 247-264; 1977.

Toxicological tests used to evaluate chemicals commonly applied to human skin are reviewed, and the results obtained with propylene glycol are presented as an example. Unfortunately, data on the cutaneous and systemic effects of applied chemicals are not complete. More effective ways of determining the hazards of these chemicals to humans must be developed. (38 refs)

78-3016 **Metabolism of Halogenated Ethylenes.** (Eng) Leibman, K. C. (Dept. Pharmacology and Therapeutics, Univ. Florida Medical Sch., Gainesville, FL, 32610); Ortiz, E. *Environ Health Perspect* 21: 91-97; 1977.

Literature on the metabolic transformations of various chlorinated ethylenes is reviewed, and the results of studies on the products of metabolism of some of these compounds are presented. The metabolism of chlorinated ethylenes may be explained by the formation of chloroethylene epoxides as the first intermediate products. These epoxides appear to rearrange with the migration of chlorine to form chloroacetaldehydes and chloroacetyl chlorides. In experiments in which 1,1-dichloroethylene, trichloroethylene, and tetrachloroethylene were incubated with rat liver microsomal systems, monochloroacetic acid, chloral hydrate, and trichloroacetic acid, respectively, were found. Rearrangements of chloroethylene glycols formed from the epoxides by hydration may also occur, but they appear, at least in the case of 1,1-dichloroethylene, to be quantitatively less important. The unstable epoxide ring formed during the metabolism of chlorinated ethylenes may react with a variety of groups in compounds of biological interest. When these compounds are essential to cellular function the reaction may lead to alteration of cellular metabolism and subsequent cell necrosis or to carcinogenic or mutagenic events. (51 refs)

78-3017 **Mutagenic and Carcinogenic Risks Associated with Halogenated Olefins.** (Eng) Infante, P. F. (Industry-Wide Studies Branch, Div. Surveillance, Hazard Evaluations and Field Studies, Natl. Inst. Occupational Safety and Health, Center Disease Control, Dept. Health, Education and Welfare, Cincinnati, OH, 45202). *Environ Health Perspect* 21: 251-254; 1978.

The mutagenicity and carcinogenicity of vinyl chloride (VC), vinylidene chloride, trichloroethylene, perchloroethylene, and chloroprene are reviewed. Of the first four compounds, all except perchloroethylene have been shown to be mutagenic in test systems, and all have induced tumors in experimental animals. Studies with chloroprene have indicated that it causes sterility in male mice and rats. Rat studies have also indicated that concentrations ranging from 0.04 to 1.0 ppm result in a dominant lethal effect, affect sperm, cause testicular atrophy, and cause chromosomal aberrations in bone marrow cells. Human studies have indicated both an increase in chromosomal aberrations and a decrease in mobility of the sperm of exposed workers. Several studies have indicated an excess of lung and skin cancer in exposed workers, and one report confirmed a case of angiosarcoma of the liver in a worker with extensive exposure to finished polychloroprene. Studies with VC have indicated that in addition to angiosarcoma, there appears to be a dose-response relationship between exposure and the induction of mammary cancer in rats. A study of women employed in the VC industry indicated a 38% excess of breast cancer in those exposed. These findings could indicate another site of VC carcinogenesis. (29 refs)

78-3018 **Perspectives in the Investigation of Health Hazards in the Chemical Industry.** (Eng) Selikoff, I. J. (Mount Sinai Sch. Medicine, City Univ. New York, Fifth Ave. and 100th St., New York, NY, 10029). *Ecotoxicol Environ Saf* 1(3): 387-397; 1977.

The prediction in the early half of this century that the synthesis of new chemicals by the chemical industry would lead to a large increase in the number of cancers has not, for the most part, been fulfilled. Further investigations in the laboratory and in industry, as well as epidemiological studies, are necessary to determine whether or not this prediction is valid. (3 refs)

78-3019 **Benzene and Leukaemia (Letter to Editor).** (Eng) Aksoy, M. (Sect. Haematology, Dept. Internal Medicine, Instanbul Medical Sch., Capa-Istanbul, Turkey). *Lancet* 1(8061): 441; 1978.

Evidence of relationship between benzene exposure and leukemia was found in several studies. Permissible exposure to benzene should be as low as possible in view of individual susceptibility, because the relation between duration of exposure and bone marrow abnormalities varies, and because abnormalities in porphyrin metabolism and lowered WBC alkaline phosphatase activity can occur at exposure levels as low as 10 ppm. (10 refs)

78-3020 **Asbestos and Cancer.** (Fre) Bignon, J. (Service de Pneumologie, Centre Hospitalier Intercommunal, 40, avenue de Verdun, F 94000 Creteil, France); Bader, J. P. *Gastroenterol Clin Biol* 2(5): 453-457; 1978.

Literature on the carcinogenic effects of asbestos, with emphasis on cancers produced in the gastrointestinal tract as a result of ingestion of fibers via drinking water and food, is reviewed. Exposure to asbestos is not limited to the working environment and cancers related to asbestos exposure are not limited to the respiratory tract and lungs. (42 refs)

78-3021 **Malignant Mesothelioma and Its Relation to Asbestos Pollution.** (Fre) Bignon, J. (Service de Pneumologie, Centre Hospitalier Intercommunal, 40, av. de Verdun, 94010 Creteil, France); Ruffie, P. *Pollut Atmos* 19(76): 367-371; 1977.

The literature on the association of asbestos and cancers of the lung and respiratory tract is reviewed. A program has been initiated by the Commission of the European Community to determine the dose-effect relationship of asbestos to cancer. Mesothelioma was selected as the tumor to be investigated, since it is rare (1-4/1,000,000 population) and 80% of the patients have a history of asbestos exposure. Epidemiologically, mesotheliomas are more likely to occur in port or large industrial cities. The av age of death from mesotheliomas is 55-60 yr, more than 10 yr younger than the av age of death from bronchopulmonary cancer. All types of asbestos except anthophyllite appear to be responsible for mesotheliomas, and cigarette smoking does not appear to be a cofactor in tumor occurrence. Registries have already been established to collect data on asbestos and mesotheliomas in Great Britain and the Netherlands. (53 refs)

78-3022 **Colorectal Cancer--An Occupational Disease?** (Eng) Jansson, B. (Natl. Large Bowel Cancer Project, M.D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030). *Gastroenterology* 75(2): 321-323; 1978.

Environmental factors that promote colorectal cancer are reviewed. These include diet, selenium deficiency, and employment in certain areas of the textile and steel industries and in industries involving contact with asbestos. (9 refs)

78-3023 **Cancer and the Environment.** (Eng) Koch, H. (Dusseldorf Univ. Hosp. Maxillo-Facial and Plastic Surgery, Moorenstrasse 1, 4000, Dusseldorf 1, W. Germany). *Int Dent J* 27(2): 154-164; 1977.

The significance of harmful exogenous substances that promote carcinogenesis is reviewed. Approx 30 of these substances are carcinogenic in humans. They include not only chemicals (industrial, domestic exposure), but also radiation (natural, diagnostic, therapeutic). Various natural carcinogens are present in plant products. Although some human tumors may be caused by viruses, most have nonviral etiologies. (14 refs)

78-3024 **Genetic Aspects of Neoplastic Diseases.** (Pol) Zbytniewski, Z. (Zaklad Biologii, Inst. Biol. Med. MM, ul. Debinki 1a, 80-211 Gdansk, Poland); Kanclerz, A. *Wiad Lek* 31(5): 327-333; 1978.

The increased pollution of the human environment by chemical carcinogens has resulted in an increased incidence of neoplasms and mutations. Most human neoplasms are due to environmental factors. (31 refs)

78-3025 **Environmental and Genetic Determinants of Cancer.** (Eng) Fraumeni, J. F. (Environmental Epidemiology Branch, NCI, Bethesda, MD, 20014). *J Environ Pathol Toxicol* 1(2): 19-30; 1977.

Patterns of human cancer that may reflect environmental and genetic contributions are summarized. Available epidemiologic data indicate that up to 90% of human cancer is influenced by environmental stimuli. The evidence from various tumors suggests that a multifactorial process, including environmental cofactors and genetic-environmental interactions, is involved in their development. Genetic predisposition is possible even for tumors with marked geographic and temporal variations, since mutant genes often require environmental exposures for expression, as in the case of xeroderma pigmentosum, galactosemia, lactase deficiency, and phenylketonuria. Clinical observations suggest that familial tendencies may predispose to leukemia following contact with benzene, to liver cancer following hepatitis B infection, and to various cancers following radiation exposure. Except in hereditary syndromes or familial cancer, a genetic predisposition is usually too subtle for detection by ordinary clinical or epidemiologic means. Appropriate biological markers need to be developed. Preliminary findings that cultured cells from lung cancer patients have increased levels of inducible aryl hydrocarbon hydroxylase activity imply that a genetically regulated enzyme defect affects the metabolism and conversion of hydrocarbons to carcinogens. (38 refs.)

78-3026 **The Molecular Biology of the Induction of the Hepatic Mixed Function Oxidases.** (Eng) Bresnick, E. (Dept. Biochemistry, Univ. Vermont Coll. Medicine, Burlington, VT, 05401). *Pharmacol Ther [A]* 2(2): 319-335; 1978.

The biological events surrounding the induction of hepatic mixed-function oxidases are reviewed. Particular attention is focused on inhibitor studies; liver growth, RNA synthesis, and induction; chromatin activation and nuclear protein profiles; protein synthesis; receptors and interaction with inducers; and nuclear activation. (94 refs)

78-3027 **Reconstituted Mammalian Mixed-Function Oxidases: Requirements, Specificities and Other Properties.** (Eng) Lu, A. Y. (Dept. Biochemistry and Drug Metabolism, Hoffmann-La Roche Inc., Nutley, NJ, 07110); West, S. B. *Pharmacol Ther [A]* 2(2): 337-358; 1978.

The requirements, specificities, and various other properties of the reconstituted mixed-function oxidase systems of several mammalian tissues are reviewed. The liver microsomal system is described in detail, and the reconstituted systems from other tissues are briefly discussed and then compared with the liver microsomal system. (136 refs)

78-3028 **Metabolism of Chemical Blastomogenic Agents and Carcinogenesis.** (Rus) Balanski, R. M. (Lab. Chemical Carcinogens, N. N. Petrov Scientific Res. Inst. Oncology, Leningrad, USSR). *Vopr Onkol* 24(2): 100-106; 1978.

In this review, literature pertaining to the effect of inducers or inhibitors of microsomal oxidation on chemical carcinogenesis is summarized. Combined application of several polycyclic aromatic hydrocarbons can reduce the total number of induced skin, pulmonary, and liver tumors in experimental animals and it can elongate the latent period of tumor development. Preliminary exposure of animals to 7,8-benzoflavone inhibited the carcinogenic effect of dimethylbenzanthracene by 39%-90%; disulfiram completely inhibited the growth of dimethylhydrazine-induced tumors of the large intestine in mice. (76 refs)

78-3029 **Diet and Intestinal Diseases.** (Eng) Vaezzadeh, K. (Dept. Surgery, Pahlavi Univ., Shiraz, Iran); Dutz, W. *Am J Proctol* 29(2): 22-25; 1978.

The high-calorie, low-bulk processed food of industrial nations may be involved in the pathogenesis of diverticulosis, ulcerative colitis, Crohn's disease, polyps, and colorectal cancer. The high-bulk, low-calorie diet of rural Asian and African populations may prevent these pathologies, but it is responsible for volvulus of the small intestine, cecum, and sigmoid colon. (21 refs)

78-3030 **Impact of Westernization on the Nutrition of Japanese: Changes in Physique, Cancer, Longevity and Centenarians.** (Eng) Kagawa, Y. (Dept. Biochemistry, Jichi Medical Sch., Minamikawachi-machi, Tochigi-ken, 329-04, Japan). *Prev Med* 7(2): 205-217; 1978.

The effects of a westernized diet on the physique, longevity, and cancer incidence of the Japanese was investigated. Between 1950 and 1975, the intake of milk (15-fold); meat, poultry, and eggs (7.5-fold); and fat (6-fold) has increased, and the consumption of barley (2.5%), potatoes (50%), and rice (70%) has decreased. This westernization is more pronounced in the younger generation and among rich people, nonfarmers, and city dwellers. However, the quantities of western foods consumed in Japan are still much less than those consumed in the US and Europe. The quality of the nutrients is also very different: amylopectin, long chain polyunsaturated fatty acids, and indigestible polysaccharides are much more abundant in the Japanese diet. During this period, the Japanese became taller and heavier. The incidence of breast, colon, and lung cancer has increased (2- to 3-fold), but that of the stomach and uterine cancer has decreased 60% and 30%, respectively. High correlations were found between total fat intake and breast cancer mortality; the highest correlation was found between per capita pork intake and breast cancer mortality. The life expectancy has been increased an av of 12 yr for men and 14 yr for women. (32 refs)

78-3031 **Lung Cancer Etiology. Critical Appraisal.** (Eng) Burrascano, J. J. (700 Park Ave, New York, NY, 10021). *NY State J Med* 78(6): 924-934; 1978.

Factors involved in the etiology of lung cancer are reviewed. Cigarette smoking is the dominant factor, with polycyclic aromatic hydrocarbons being the major contributors to tobacco carcinogenicity. Others include industrial products, chemicals, and metals. Experimental and epidemiologic evidence shows a positive relationship between radiation and respiratory cancer. The role of viruses in these tumors is uncertain. The role of the immune system in the etiology and behavior of lung tumors is discussed. (158 refs)

78-3032 **Cancer Epidemiology. Part 11. Breast Cancer.** (Eng) Friedman, R. (Wisconsin Clinical Cancer Center, 1900 University Ave., Madison, WI, 53705); Harberg, J.; Buchanan-Davidson, D. J. *Wis Med J* 77(5): 14-15; 1978.

Risk factors, precancerous conditions, and possible causal agents of breast cancer are reviewed. The risk factors include family history of breast cancer and ages at first childbirth, menarch, and menopause. Precancerous conditions include gross cystic disease, multiple intraductal papillomas, and lobular neoplasia. Possible causal agents include dietary fat and estrogen intake. (36 refs)

78-3033 **Retinoblastoma: A Prototypic Hereditary Neoplasm.** (Eng) Knudson, A. G. (Inst. Cancer Res., Fox Chase Cancer Center, Philadelphia, PA, 19111). *Semin Oncol* 5(1): 57-65; 1978.

Data on the hereditary and nonhereditary forms of retinoblastoma are reviewed. It is estimated that 60% of all cases are nonhereditary and the remainder are hereditary. Most retinoblastoma gene carriers develop bilateral tumors; however, 5% of the carriers do not develop tumors, and some carriers have not only bilateral tumors, but also multiple tumors in one eye. The incidence of retinoblastoma is approx 5/100,000 children. It is suggested that two factors are involved in tumor development: a mutation (in germinal cells in hereditary forms or in somatic cells in nonhereditary forms) followed by some sort of stimulus (possibly another mutation). Karyotypic studies have indicated that the primary mutation in both forms appears to be associated with chromosome 13. Retinoblastoma never develops after the age of 10. This is undoubtedly related to the fact that cell division and DNA synthesis normally cease in the retinoblast cell line as differentiation proceeds. It is suggested that the tissue specific function that is altered by the retinoblastoma mutation affects DNA synthesis indirectly. (17 refs)

78-3034 **Biological Features of Tumor Progression.** (Rus) Shapot, V. S. (Cancer Res. Center, Moscow, USSR). *Vestn Akad Med Nauk SSSR* (10): 19-24; 1977.

Characteristic features of various stages of tumorigenesis are discussed with special attention to the Fould's theory. It is suggested that Fould's principle of the independent origin and development of tumor traits should be supplemented by the notion of the inequality of these traits. All tumor traits can be divided into primary (uncontrollable growth) and secondary types. The latter, in turn, can be subdivided into optional (metastatic spread, anaplasia, chromosome aberrations) and obligatory (invasive and destructive growth, systemic effect on the organism) ones. The idea that the biochemical dedifferentiation of malignant tissue (anaplasia) is, in fact, a secondary optional trait in tumorigenesis was confirmed in a series of experiments on the hormone-induced synthesis of tyrosine aminotransferase and tryptophan pyrrolase in rats with Zajdela's hepatoma. (5 refs)

78-3035 **The Urothelium: A Battleground for Oncogenesis.** (Eng) Melicow, M. M. (Uropathology Res., Columbia Univ. Coll. Physicians and Surgeons, New York, NY). *J Urol* 120(1): 43-47; 1978.

The urothelium, a term that should replace the label transitional cell epithelium, bears the brunt of attacks by various carcinogens in the urine. It is postulated that the attack is on the asymmetric unit membrane and the Golgi complex or other coding units and that it results in the destruction of the mechanism for specialization of the urothelial cell. The anaplastic cancer cell is a return to the unicellular state. Cancers in which a deficiency of the specialization function has been observed or is suspected are listed. (24 refs)

78-3036 **Problems Concerning the Morphogenesis of Colorectal Cancer.** (Rus) Pozharisskii, K. M. (N. N. Petrov Res. Inst. Oncology, USSR Ministry Public Health, Leningrad, USSR). *Arkh Patol* 40(5): 76-84; 1978.

Analysis of the literature shows that there is no reliable evidence of an association between intestinal adenomatous polyps and the morphogenesis of colorectal cancer. On the other hand, villous and glandular-villous tumors often undergo malignant transformation. The growth pattern as well as the histological, ultrastructural, histochemical, immunological, and other characteristics of these tumors are similar to those of adenocarcinomas. Therefore, villous tumors without invasion can be referred to as carcinoma in situ or superficial cancer. (80 refs)

78-3037 **The Epidemiology of Cervical Cancer.** (Eng) Barberis, L. (Direzione Sanitaria, Ospedale Maggiore di Bergamo, Bergamo, Italy); Bertocchi, C. *Minerva Ginecol* 30(4): 291-298; 1978.

Recent epidemiological and etiological studies of carcinoma of the uterine cervix are reviewed. Early sexual activity and sexual promiscuity have been shown to increase the incidence of cervical carcinoma. Barrier contraceptives and circumcision are believed to have no effect on this incidence. With respect to the latter, the lower incidence among Jewish women may be due to racial or genetic factors. The carcinogenicity of sex hormones has been proved in animals, but not in humans. Statistics show that there is a relationship between herpes simplex virus type 2 and cervical carcinoma, but an etiological role for oral contraceptives is uncertain. Microbial inflammations may be a cause of precancerous conditions or of a predisposition to cervical neoplasia. (20 refs)

78-3038 **Epidemiological Approaches to Determining Whether Herpesvirus Is the Etiological Agent of Cervical Cancer.** (Eng) Melnick, J. L. (Dept. Virology and Epidemiology, Baylor Coll. Medicine, Houston, TX, 77030); Adam, E. *Prog Exp Tumor Res* 21: 49-69; 1978.

Evidence suggestive of an etiological role for herpes simplex virus type 2 (HSV-2) in cervical cancer is reviewed, and epidemiological approaches to further investigations are proposed. HSV-2 infection and cervical cancer affect women with similar sexual attributes, suggesting a venereal transmission of the virus. Immunofluorescence techniques have demonstrated the presence of herpesvirus antigens in cells exfoliated from lesions of squamous cell carcinoma of the cervix. Antigens were also reported in cells from lesions of carcinoma in situ (CIS) and lesser degrees of atypia. Infectious HSV-2 was also recovered from a cell line derived from a CIS lesion. The prevalence of HSV-2 antibodies in patients with invasive cancer varied from 31%-100%; the range in controls was 13%-67%. In CIS patients, antibodies were present in 32%-100% vs 14%-53% in controls. In subjects with dysplasia, the range was 24%-95% vs 14%-44% in controls. The relative risk of invasive carcinoma of the cervix in women with HSV-2 antibodies ranged up to 10 times that in women without antibodies. Serological data indicate that: (1) HSV-2 infection may be etiologically associated with only some cervical neoplasia cases, suggesting multiple etiologies; (2) there may be geographical differences in conditions for the sequence of infections with different types of herpesvirus; (3) antigenically different HSV-2 strains may have a different geographic distribution; and (4) the association of HSV-2 infection and cervical neoplasia is not an etiologic one. In case control studies of antibodies to nonvirion antigens, antibodies to the soluble antigen isolated from cancer cells of the lower genital tract of 95% of patients and 25% of controls reacted with HSV-2 antisera prepared in guinea pigs. Cervical cancer patients also had a greater serum reactivity to VP134 antigen than patients with breast cancer and controls. Antibodies to HSV-2-induced specific antigen were found in 91% of invasive carcinoma, 68% of CIS, and 35% of atypia patients and 9% of controls. The data support an etiological relationship of HSV-2 infection to at least some cervical neoplasias. (69 refs)

78-3039 **The Genital Herpes-Cervical Cancer Hypothesis--10 Years Later.** (Eng) Nahmias, A. J. (Dept. Pediatrics, Emory Univ. Sch. Medicine, Atlanta, GA, 30303); Sawanabori, S. *Prog Exp Tumor Res* 21: 117-139; 1978.

Studies related to the hypothesis that genital herpes simplex virus (HSV) infection is in some way associated with cervical cancer are reviewed. The various topics include the epidemiological aspects, the temporal relationship, clinicopathological aspects, HSV strain differences, the oncogenic potential of HSV, HSV markers in neoplastic cells, and seroepidemiological studies and assays for cell-mediated immunity. The results that have been obtained are extremely variable. Although this may indicate that the association between viral infection and cervical cancer is a spurious one, it may also indicate the complexity of the problem and of the methodologies employed. (120 refs)

78-3040 **Viruses and Human Cancer: The History and Current Status of ESP-1.** (Eng) Dmochowski, L. (Dept. Molecular Carcinogenesis and Virology, Univ. Texas System Cancer Center, Texas Medical Center, Houston, TX, 77030); Bowen, J. M. *Prog Exp Tumor Res* 21: 160-195; 1978.

Current knowledge of ESP-1 virus, isolated from the pleural effusion cells (ESP-1 cells) from a 5-yr-old boy with American-type Burkitt's lymphoma, is reviewed. Electron microscopy of cells from the 10th tissue culture passage revealed the presence of C-type virus particles in varying stages of development. Human leukocyte antigen (HLA) studies of the ESP-1 cells indicated that the HLA types were entirely compatible with those of the parents; ie, that the tissue culture cells contained surface antigens shared with the mother and father. Sera of 265 cancer patients and 180 normal individuals were tested by indirect immunofluorescence assays for antibodies to ESP-1 cell-associated antigens. The highest frequencies of positive reactions were observed with sera from patients with Burkitt's lymphoma (African and American), reticulum cell sarcoma, and rhabdomyosarcoma; only 2/180 normal donor sera were positive. ESP-1 virus has the typical morphology of mammalian C-type viruses, with the mean diameter of the mature virion being 100 nanometers. The buoyant density of the ESP-1 virions in isopycnic gradients is 1.14-1.17 g/cm^3; the virion RNA has a mean sedimentation value of 68S, and it separates into subunits of 28S and 35S upon heating. The virus contains a reverse transcriptase with the characteristic properties of a C-type virus enzyme. However, thus far, it has demonstrated a total lack of infectivity for other cells in tissue culture. The major identifiable antigenic determinants of ESP-1 virus are murine. (78 refs)

78-3041 **An Assessment of the Possible Role of Viruses in the Aetiology of Burkitt's Lymphoma.** (Eng) Epstein, M. A. (Dept. Pathology, Univ. Bristol Medical Sch., University Walk, Bristol BS8 1TD, England). *Prog Exp Tumor Res* 21: 72-99; 1978.

The role of Epstein-Barr virus (EBV) in the etiology of Burkitt's lymphoma (BL) is reviewed. Different techniques have demonstrated that the DNA and antigens of EBV are present in the cells of almost every African BL and in a minority of sporadic BL. Furthermore, the absence of virus particles in the cells in vivo and the integration of at least some virus DNA molecules into the host cell genome follow the pattern seen with known animal oncogenic DNA viruses in relation to the cells of the tumors they cause. African BL has long been recognized as a monoclonal disease, and the presence of the virus DNA in every tumor cell indicates that the original cell undergoing malignant transformation must have been infected at the outset. Antibody responses in African BL and some cases of sporadic BL fulfill criteria for a putative human tumor virus in being both always present and greatly raised in titer in the tumor patients compared with controls. Cell lines arising either by the exposure of lymphocytes from seronegative donors to EBV or by a two-step mechanism from the B cells of seropositive donors differ from BL-derived lines in cell morphology, growth characteristics, and karyotype. These observations indicate that changes brought about by the virus when conferring the power of unlimited proliferation on virus-free lymphocytes in vitro resemble those of malignant transformation by known oncogenic animal viruses. The finding that EBV causes fatal, malignant reticuloproliferative disease on inoculation into South American subhuman primates fulfills the last criterion for a putative human tumor virus. Although this finding does not prove that the virus plays an etiological role in BL, it does show that it can be directly carcinogenic in vivo. (186 refs)

78-3042 **Do Normal Human Cells Express RNA Tumor Virus-related Information?** (Eng) Gerard, G. F. (Inst. Molecular Virology, Saint Louis Univ. Sch. Medicine, St. Louis, MO, 63110); Green, M. *Prog Exp Tumor Res* 21: 250-269; 1978.

Normal human cells were examined for the presence of RNA tumor virus-related information, and the results are discussed along with those found in the literature. In general, attempts to detect RNA tumor virus-related components in normal human cells and tissues have been unsuccessful. Particle-associated reverse transcriptase (RT) has been detected in the cytoplasm of several kinds of human tumors, and a new DNA polymerase present at 1% of the level of DNA polymerase γ has been detected in cultured human cancer cells. Several observations are compatible with a role for RT-containing particles in specialized cellular functions. C-type particles have been visualized in normal human placenta, but attempts to detect RT have failed. Particles with some of the morphological and biochemical properties of RNA tumor viruses and enzyme activity similar to RT have been found in normal human milk. Recently, an endogenous DNA polymerase with RT-like activity has been found in human sperm. Nucleic acid hybridization and immunological studies, respectively, have produced evidence compatible with: (1) endogenous human genetic information distantly related to baboon C-type virus and (2) widespread infection with viruses that cross-react with two groups of subhuman primate C-type viruses. The relationship of putative endogenous human 'virogenes' and unidentified exogenously spread human viruses to human neoplasia is unknown. (76 refs)

78-3043 **Evidence for the Presence of RNA Tumor Virus Components in Human Leukemia.** (Eng) Gallo, R. C. (Lab. Tumor Cell Biology, Div. Cancer Treatment, NCI, NIH, Bethesda, MD, 20014); Meyskens, F. L. *Prog Exp Tumor Res* 21: 216-249; 1978.

Evidence for the involvement of RNA tumor viruses in human myelogenous leukemia is reviewed. Components related to murine and primate (woolly monkey and baboon) RNA tumor viruses have often been identified in the peripheral WBC and tissues of untreated patients with acute myelogenous leukemia and chronic myelogenous leukemia in the acute phase. These components are: (1) a reverse transcriptase with significant homology to woolly monkey (simian sarcoma virus; SiSV) and partial homology to murine (Rauscher murine leukemia virus; R-MuLV) reverse transcriptase; (2) viruslike intracellular particles that fractionate isopycnically at 1.17 g/ml in sucrose and can in some cases be converted to 1.23-g/ml cores, have a sedimentation coefficient of 550S, have a diameter of 500-1,000 A, can generate virus-related complementary DNA sequences in an endogenous reaction, and have nucleic acids with viruslike properties; (3) R-MuLV-, baboon endogenous virus (BaEV)-, and SiSV-related sequences, which have been detected in the DNA of some leukemic tissue but not in that of normal tissue; (4) viruslike particles that have demonstrated homology to SiSV and BaEV; (5) a virus, isolated several times from a single patient, that contains both SiSV- and BaEV-related components. (126 refs)

78-3044 **Transport Alterations in Virus-transformed Cells.** (Eng) Parnes, J. R. (Dept. Medicine, Harvard Medical Sch., Boston, MA, 02114); Isselbacher, K. J. *Prog Exp Tumor Res* 22: 79-122; 1978.

Studies of the changes in transport that occur with the transformation of mammalian cells are reviewed, especially those in which membrane vesicles were used. The data show that viral transformation results in the enhanced transport of specific nutrients, but it is not known whether these changes play a primary or secondary role in transformation. (164 refs)

78-3045 **Virus-Virus Cocarcinogenesis and Other Aspects of Virus Interaction.** (Rus) Mazurenko, N. P. (Cancer Res. Center, Moscow, USSR); Merekalova, Z. I.; Iakovleva, L. S.; Seniuta, N. B.; Kiselev, F. L.; Pavlovskaia, A. I.; Topol', L. Z.; Plakhov, I. V.; Lavrov, S. V.; Nikitin, A. M.; Stepina, V. N.; Zakharova, O. S. *Vestn Akad Nauk SSSR* (5): 65-73; 1978.

Various aspects of viral cocarcinogenesis and the interaction between oncogenic and infectious viruses are summarized. The phenomenon of virus-virus cocarcinogenesis was first demonstrated in 1955, when 20% of CC57Br mice (low incidence of leukemia) inoculated with smallpox virus developed leukemia. In another study, smallpox virus was isolated from primary or continuous cultures of diffuse polyposis cells from human large intestine. The ability of some infectious viruses to activate latent oncogenic viruses and induce the expression of viral proteins was further confirmed in studies of the superinfection of BALB/c embryonal fibroblast cultures infected with Friend leukemia virus (FLV) or Moloney sarcoma virus. Superinfection with Sendai virus, influenza virus or herpesvirus significantly increased the production of the leukemia and sarcoma viruses. Simultaneous cultivation of FLV with Sindbis virus inhibited production of the latter; the inhibition was probably due to the FLV-induced production of interferon. Specific interaction was also discovered between the attenuated and pathogenic variants of Marek's disease virus. (25 refs)

78-3046 **Membrane Proteins of Cells Neoplastically Transformed by Simian Virus 40.** (Eng) Schmidt-Ullrich, R. (Therapeutic Radiology Dept., Radiobiology Div., Tufts-New England Medical Center, 171 Harrison Ave., Boston, MA, 02111); Wallach, D. F. *Prog Exp Tumor Res* 22: 151-189; 1978.

Studies of membrane-protein anomalies in cells neoplastically transformed by simian virus 40 (SV40) and of the possible role of SV40-specific proteins for abnormal membrane structure and function are reviewed. The findings are consistent with the possibility that it is the insertion of the SV40-specific membrane proteins that modifies the collective thermotropic behavior of both membrane proteins and membrane lipids, although nonspecific mechanisms are also possible. (83 refs)

78-3047 **Recombination Events Between Simian Virus 40 and the Host Genome.** (Eng) Winocour, E. (Dept. Virology, Weizmann Inst. Science, Rehovot, Israel); Oren, M.; Lavi, S.; Vogel, T.; Gluzman, Y. *Miami Winter Symp* 14: 181-196; 1977.

During the replication of simian virus 40 (SV40) in monkey cells, large portions of the viral genome are replaced by covalently linked cellular DNA sequences. The passage history of three independently generated substitute SV40 populations, CVB-1-P-4, CVB-4-P8, and CVG-1-P10, is reviewed with emphasis on the isolation of a clonal CVB-1-4 variant (F161-F). The structure of the F161-F DNA was investigated by restriction endonuclease mapping and hybridization techniques. The results indicate that 61% of the total DNA sequences are of host origin and are interspersed between four repeated viral units. Preliminary data on the four host segments suggest they share common sequences and that they code for only 16,000-18,000 daltons of protein. The use of marker rescue experiments to study recombination events between endogenous and exogenous SV40 genes is also discussed. In these experiments, the DNA of marker-rescued virus was analyzed by restriction endonuclease mapping to determine whether it contained segments of both the endogenous virus (SV40 strain 777) genome of transformed cells and the exogenous superinfecting temperature-sensitive (*ts*) mutant. Virus rescue was observed only with *tsA* mutants, but the level was very low. This result is consistent with the concept that the endogenous SV40 genome is defective in the function required for initiation of viral DNA synthesis. (20 refs)

78-3048 **Cell Surface Markers.** (Eng) Cantor, H. (Harvard Medical Sch.-Farber Cancer Center, Boston, MA, 02115). *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 323-326; 1978.

The importance of T cells to tumor immunity is reviewed. The specific topics include the cell-surface phenotypes of normal and leukemic T and B cells, interactions among lymphocyte sets, and characteristics of the immune response to murine sarcoma virus-induced lymphomas and leukemias. (6 refs)

78-3049 **Immunosuppressive Phenomena in Experimental Tumor Systems.** (Fre) Reme, T. X. (Dept. d'Immunologie Clinique et Experimentale, Centre Paul Lamarque, Hopital St-Eloi, 34033 Montpellier, France). *Pathol Biol (Paris)* 25(10): 735-740; 1977.

The immunosuppressive role of T lymphocytes and macrophages and/or their secretions in the growth of various spontaneous, chemically induced, or virally induced animal tumors is reviewed. Numerous studies have established the ability of T lymphocytes from tumor-bearing animals to block tumor rejection in syngeneic immunized animals. In vitro studies have demonstrated the suppressive effect of T lymphocytes from tumor-bearing animals on cell-mediated immune reactions. Splenocytes, thought to be macrophages, from rats carrying nonviral tumors do not respond to stimulation by phytohemagglutinin (PHA). Other studies have investigated the immunosuppressive activity of serum from tumor hosts without determining the exact nature of the complex responsible for the immunosuppression or its relation to T cells or macrophages. The mechanism of immunosuppression is discussed with respect to the production of antigens by tumor cells, whether these antigens are virus-related, and the relationship between the antigens and the reaction of suppressor cells to stimulation by PHA and other mitogens. (80 refs)

78-3050 **Etiology of Human Leukemias.** (Rus) Vorob'ev, A. I. (Dept. Hematology, Central Inst. Advanced Training Physicians, Moscow, USSR); Brilliant, M. D. *Ter Arkh* 50(7): 3-10; 1978.

Problems related to the etiology of human leukemias are discussed. External factors that may lead to the development of chronic and acute myeloid leukemia include ionizing radiation and chemical mutagens (including some cytostatic antitumor drugs). Severe immunodepression caused by treatment with cytostatics, total irradiation, or antilymphocyte serum increases the incidence of lymphosarcomas markedly. (76 refs)

78-3051 **Some Thoughts on Moles and Melanomas.** (Eng) Whiting, D. A. (Section Dermatology, Univ. Texas Health Science Center at Dallas, 5323 Harry Hines Blvd., Dallas, TX, 75235). *Int J Dermatol* 17(6): 485-487; 1978.

Moles on the trunk may be more susceptible to malignant change than moles elsewhere. In one study, a correlation was found between melanoma on the trunk and the presence of nevus cells in the lesion. Most of the nevus cell-containing melanomas were presumed to have developed in junctional nevi, which have a predilection for the trunk. Speculations are made on the role of UV light in the development of melanomas. (5 refs)

78-3052 **The Time Factor in Carcinogenesis. The 1977 Sievert Lecture.** (Eng) Mayneord, W. V. (7 Downs Way Close, Tadworth, Surrey, KT20 5DR, England). *Health Phys* 34(4): 297-309; 1978.

The time factor in radiation carcinogenesis is discussed in relation to Sievert's concept that the latent period depends on the radiosensitivity of the cell and the speed of reconstitution of essential cell ingredients. Dose-response curves for chemical carcinogens and radiation are compared, and examples are given of the lognormal distribution of time delay and cancer. Experiments with low linear-energy-transfer radiation suggest that the dose response of tumor-resistant tissue is curvilinear or sigmoid, but that of sensitive tissue is linear. Sensitive tissue corresponds to a low median dose (or time) and a large variance (ie, population heterogeneity). Because a probability density function can be assumed for the latent period, a combination of cell survival and probable tumor incidence can be used to predict the peak response. The possibility that the latent period may be reduced by noncarcinogenic promotors or viruses is noted. (23 refs)

78-3053 **A Current Literature Report on the Carcinogenic Properties of Ionizing and Non-ionizing Radiation. I. Optical Radiation.** (Eng) Cunningham-Dunlop, S. (Franklin Inst. Res. Lab., Science Information Services, Philadelphia, PA, 19103); Kleinstein, B. H. (Washington: U.S. Government Printing Office): DHEW (NIOSH) Publication No. 78-122, 90 pp.; 1977.

Carcinogenic hazards of occupational exposure to UV, visible, and infrared radiation are presented based on a review of the literature published since 1970. The types of cancer induced by optical radiation in man and laboratory animals, proposed radiocarcinogenic mechanisms, dose-response relationships, wavelength dependence, and synergistic effects are covered. The risk of excess radiation-induced cancer under commonly encountered conditions of occupational exposure to UV is estimated. Specific gaps in the present knowledge of radiation carcinogenesis are identified, and specific areas in need of further investigation are recommended. (137refs)

78-3054 **Histogenesis of Chemically and Radiation-induced Carcinogenesis of the Respiratory Tract (Meeting Abstract).** (Eng) Smith, D. M. (No affiliation given). *Am J Med Technol* 44(5): 491; 1978. (no refs)

78-3055 **Xeroderma Pigmentosum: Genetic and Environmental Influences in Skin Carcinogenesis.** (Eng) Cleaver, J. E. (Lab. Radiobiology, Univ. California Medical Sch., San Francisco, CA, 94143). *Int J Dermatol* 17(6): 435-444; 1978.

The biochemical, cellular, and clinical characteristics of xeroderma pigmentosum, an excision repair-defective disease, are reviewed to provide a better understanding of one kind of carcinogenesis, in which an accumulation of genetic damage is theorized to be part of the underlying mechanisms. If damage in some critical region(s) of the genome is not repaired or is repaired inaccurately before DNA replication occurs, the region may become the site of a somatic mutation. (47 refs)

78-3056 **Fetal Patterns in Adult Rat Liver Undergoing Reparative and Neoplastic Changes (Meeting Abstract).** (Eng) Uriel, J. (Institut de Recherches sur le Cancer, Villejuif, France). *Digestion* 16(3): 280; 1977. (no refs)

78-3057 **Relation of Lectin-induced and Spontaneous Adhesion to Tumorigenicity.** (Eng) Wright, T. C. (Dept. Pathology, Harvard Medical Sch., 25 Shattuck St., Boston, MA, 02115); Ukena, T. E.; Karnovsky, M. J. *Prog Exp Tumor Res* 22: 1-27; 1978.

Studies of intercellular adhesive interactions mediated by ligands such as plant lectins and spontaneous aggregation occurring between cells in suspension are reviewed, and differences in the adhesion of normal and transformed cells are surveyed. Transformation-related membrane changes, which affect cell-cell and cell-substratum adhesiveness, appear to be one of the most clear-cut systems for demonstrating surface differences between the two cell types. (98 refs)

78-3058 **A Single Protein Key to Cancer?** (Eng) Durham, A. (Institut de Biologie Moleculaire et Cellulaire, CNRS, Strasbourg, France). *New Sci* 77(1096): 860-862; 1978.

A hypothetical mechanism by which a transforming protein may affect cellular transformation is proposed. In this model, the oncoprotein is integrated into the cellular membranes and acts directly or indirectly as an ion channel. Altered ion concentrations cause more oncoprotein to be made and the cell is trapped in a cycle of positive feedback. Under these conditions, the virus would fluorish but the cell would fare badly. (no refs)

78-3059 **Polyamines in Rapid Growth and Cancer.** (Eng) Janne, J. (Dept. Biochemistry, Univ. Helsinki, SF-00170 Helsinki 17, Finland); Poso, H.; Raina, A. *Biochim Biophys Acta* 473(3/4): 241-293; 1978.

Studies of the role of the natural aliphatic polyamines putrescine, spermidine, and spermine in cell proliferation and neoplastic processes are reviewed. Topics covered include: the relation of polyamine synthesis and accumulation to cell cycle and proliferative activity, the relation of the biological effects of polyamines to their postulated physiological functions, the occurrence of polyamines in rapidly growing animal tissues during developmental and compensatory growth, the effect of growth-promoting hormones on the synthesis and metabolism of polyamines in various tissues, polyamine synthesis and accumulation in experimental animal tumors, and the presence of polyamines in human tissues and fluids in various types of cancer. Embryonic and other rapidly growing tissues, both normal and neoplastic, contain high concentrations of polyamines, and the experimental evidence at present indicates that natural polyamines play an essential role in cellular metabolism and in cell proliferation in particular. The use of selective inhibitors of polyamine synthesis as specific antiproliferative agents may have practical therapeutic applications, and measurements of polyamines in physiological fluids may serve as useful markers of human malignancies. (426 refs)

78-3060 **Cancer and Mental Illness (Letter to Editor).** (Eng) Roppel, R. M. (Biomechanics Dept., Michigan State Univ., East Lansing, MI, 48824). *Science* 201(4354): 398; 1978.

The fact that mental patients have a greatly reduced incidence of cancer (vs the general population) may be due to a breakdown of cybergenetic mechanisms, a psychotherapy agent with antitumor effects, a common immunological factor, a factor in the mental hospital environment, or a genetic factor. There is no evidence that favors one of these explanations over the others. (8 refs)

78-3061 **An Evaluation of 6 Short-Term Tests for Detecting Organic Chemical Carcinogens.** (Eng) Purchase, I. F. (Imperial Chemical Industries Ltd., Central Toxicology Lab., Alderley Park, Cheshire, England); Longstaff, E.; Ashby, J.; Styles, J. A.; Anderson, D.; Lefevre, P. A.; Westwood, F. R. *Br J Cancer* 37(6): 873-903; 1978.

The ability of the following six short-term tests to predict the carcinogenicity of 120 organic chemicals was compared: mutation of *Salmonella typhimurium*, cell transformation, degranulation of endoplasmic reticulum, sebaceous gland suppression, tetrazolium reduction, and sc implant. The chemicals included 50 carcinogens and 62 noncarcinogens, and they were divided into four broad chemical classes. All tests but the tetrazolium test showed some ability to discriminate between carcinogens and noncarcinogens, with the cell transformation and bacterial mutation tests being the most accurate (94% and 93%, respectively). The use of cell transformation and bacterial mutation together provided an advantage over the use of either test alone, but the inclusion of the other four tests in a screening battery resulted in a great increase in overall inaccuracy and loss of discrimination. False-negative and false-positive results can be minimized by using appropriate chemical class controls to identify the test that is optimal for the class in question. Structural analogy may play a part in the rapid detection of environmental carcinogens, and some general guidelines for its use are given. (39 refs)

78-3062 **The Tetrazolium-Reduction Test.** (Eng) Westwood, F. R. (Imperial Chemical Industries Ltd., Central Toxicology Lab., Alderley Park, Cheshire, England). *Br J Cancer* 37(6): 949-953; 1978.

A modified tetrazolium-reduction technique was evaluated for its ability to predict the potential carcinogenicity of 120 organic chemicals. Seven drops of a benzene soln of each compound were applied to the clipped dorsolumbar region of male Swiss-derived Alderley Park mice. Differences in tetrazolium reducton that would occur as a result of using hirsute rather than hairless mice were reduced by using 6- to 8-wk-old animals rather than 12- to 15-wk-old animals. The skin was sampled at various times after treatment, and a 2-day interval was found to be optimum. A compound was considered positive (carcinogenic) if there was a significant increase in the amount of formazan deposited in the skin, and a compound was considered negative if there was a significant decrease in formazan deposition or no significant change from control. (The amount of formazan deposited is directly proportional to the oxygen consumption of tissues or cells). The results agreed with those predicted from the literature for only 66/120 compounds. False-negative results were obtained with 36/58 carcinogens and false-positive results were obtained with 18/62 noncarcinogens. (12 refs)

78-3063 **The Degranulation Test.** (Eng) Lefevre, P. A. (Imperial Chemical Industries Ltd., Central Toxicology Lab., Alderley Park, Cheshire, England). *Br J Cancer* 37(6): 937-943; 1978.

The effectiveness of the degranulation test for predicting the carcinogenic potential of 120 organic chemicals was determined. The use of membranes containing radiolabeled RNA for monitoring ribosome loss was also evaluated. Portions of rough and smooth endoplasmic reticulum (RER and SER, respectively) from male Wistar rats were incubated with the test compounds, and the extent of degranulation was measured. More than 90% of the radioactive label administered in vivo was associated with the RNA in both RER and SER, and the ribosomal RNA was uniformly labeled. The results confirm that radioactivity can be equated with RNA content. Of the 58 carcinogens tested, 41 gave a positive result in the degranulation test, and a correct negative result was obtained with 44/62 noncarcinogens tested. There was no apparent correlation between the extent of degranulation and carcinogenic potency, and the test was not specific for liver carcinogens. It is necessary to choose dose levels with care in degranulation assays, because increasing the carcinogen concentration above a certain level decreases the degranulation. (21 refs)

78-3066 **Differences in Metabolism of Vinylidene Chloride Between Mice and Rats.** (Eng) Jones, B. K. (Central Toxicology Lab., Imperial Chemical Industries, Alderley Park, Cheshire SK10 4TJ, England); Hathway, D. E. *Br J Cancer* 37(3): 411-417; 1978.

The metabolism of vinylidene chloride (1,1-dichloroethylene, DCE) was investigated in male Alderley Park rats and male Alderley Park mice. Following a single po dose of 50 mg/kg, pulmonary excretion of unchanged DCE accounted for 28% of the dose in rats, but for only 6% in mice. This suggested that the efficiency of DCE metabolism follows the known activity of cytochrome P-450 in the organs of mice, that the real exposure (expressed as amount of DCE metabolized) is relatively higher for orally dosed mice than rats, and that DCE is more likely to be carcinogenic in mice than rats. The mice metabolized DCE similarly to rats, but differences were noted. Qualitatively, mice, but not rats, excreted a small amount of N-acetyl-S-(2-carboxymethyl)cysteine. Quantitatively, (1) the relative proportions of the N-acetyl-S-cysteinylacetyl derivative that were formed in mice and rats paralleled the activity of liver glutathione-S-epoxide transferase, and (2) there were marked differences in the proportions of DCE metabolites belonging to the chloroacetic acid branch of the metabolic pathway. A tracer study verified the β-thionase hydrolysis of thiodiglycollic acid and the biogenesis of the N-acetyl-S-cysteinylacetyl derivative. It is suggested that the metabolites 1,1-dichloroethylene oxide and chloroacetyl chloride may be important in murine DCE carcinogenicity. (19 refs)

78-3067 **Pulmonary Tumors Induced in Mice by Vinyl Chloride Monomer.** (Eng) Suzuki, Y. (Environmental Science Lab., Mount Sinai Sch. Medicine, Fifth Ave. and 100th St., New York, NY, 10029). *Environ Res* 16(1/3): 285-301; 1978.

The incidence of lung tumors due to vinyl chloride (VC) inhalation was studied in 27 CD1 Charles River male mice, and precancerous changes and the resulting tumors were characterized ultrastructurally. The mice were exposed to 2,500 or 6,000 ppm VC 5 hr/day, 5 days/wk, for 5 or 6 mo and then sacrificed 2, 6, or 37 days later. Pulmonary tumors were found in 26/27 mice but in none of the 16 controls. The tumors were round, whitish, multiple, and variable in size from 1 to 5 mm in diameter. The tumors were arranged in tubulopapillary or adenomatous formations. There were no metastases to regional lymph nodes or other organs, parenchymal fibrosis, or fibrotic adhesions of the pleura, although occasional mitotic divisions and invaginations in the bronchiolar lumen were noted. Under the electron micr scope, the characteristic features of the neoplastic cells we short microvilli, tight junctions between two adjacent cell osmiophilic lamellar bodies, large irregularly shaped mit chondria, well-developed Golgi complexes, continuous discontinuous basement membranes, occasional appearan of sequestration and of crystalloids, and a lack of cilia an mucous secretory granules. Some of the cells were poorl differentiated and were equipped with poorly developed o ganoids, without the formation of osmiophilic lamellar b dies. The gross anatomical and histological aspects of th tumors indicated that they were alveologenic tumors. Th neoplastic cells were assumed to have been transformed fro type II alveolar epithelium via its hyperplastic form, becaus of the ultrastructural similarities between normal type II cell and the neoplastic cells. It is concluded that the mouse lun is a sensitive indicator of the oncogenicity of VC. (40 refs

78-3068 **Mutagenic Effects of Vinyl Chloride on *Droso phila melanogaster* with and Without Pretreat ment with Sodium Phenobarbiturate.** (Eng) Magnusson, J (Environmental Toxicology Unit, Wallenberg Lab., Univ Stockholm, Stockholm, Sweden); Ramel, C. *Mutat Res* 57(3) 307-312; 1978.

Exposure of wild-type Karsnas 60 Drosophila males (0- days old) to 10,000, 100,000 or 200,000 ppm vinyl chlorid (VC) gas increased the number of complete and mosai sex-linked recessive lethals. A threshold effect was observe that may be due to a limit of the mixed-function oxidas activity. In additional experiments, Drosophila were pretreated with a 1% soln of phenobarbital sodium (PB) dissolve in water containing 1% sucrose for 24 hr, followed immediately by exposure to 1,000 or 100,000 ppm VC gas (Grou 1). Group 2 was treated with either concentration of VC alone, and Group 3 was not treated. PB pretreatment enhanced the number of recessive lethals over the numbers produced by Groups 2 and 3. Compared with Groups 2 (corresponding group) and 3, the total number of recessive lethals produced by PB + 10,000 ppm VC was significant, but not the number produced by PB + 100,000 ppm VC. In Groups 1 and 2, the higher VC dose did not produce a higher frequency of recessive lethals than the lower dose; again, there was a lack of a dose-response effect. The results indicate that the mixed-function oxidase system can be induced in Drosophila in the same way as in mammals. (12 refs)

78-3069 **Ten Cases of Angiosarcoma of the Liver in Shawinigan, Quebec.** (Eng) Delorme, F. (Dept. Pathology, Centre Hospitalier Regionale de la Maurice, Shawinigan, Quebec, Canada); Theriault, G. *J Occup Me* 20(5): 338-340; 1978.

f the 10 cases of angiosarcoma of the liver diagnosed in hawinigan, Quebec, since 1955, all occurred in men who orked in a vinyl chloride (VC) polymerizing plant. All 10 en were very light drinkers, and only 4 smoked one or more acks of cigarettes per day. The time between the first expo- re of VC monomer and the diagnosis of angiosarcoma nged from 11 to 29 yr, with an av of 20.5 yr. Exposure to C monomer in the plant, although not documented, is be- eved to have been very high in the past. The benign liver sions found in these workers included portal and erisinusoidal fibrosis. (15 refs)

8-3070 **Mutagenicity of Vinyl Chloride. External Chromosome Studies on Persons with and With- ut VC Illness, and on VC Exposed Animals.** (Eng) Fleig, . (Dept. Occupational Medicine and Health Protection, ASF Aktiengesellschaft, 6700 Ludwigshafen, W. Ger- any); Thiess, A. M. *J Occup Med* 20(8): 557-561; 1978.

hromosome analysis was performed on lymphocyte cultures rom 6 workers with an estimated degree of exposure to vinyl hloride (VC), 4 workers whose degree of exposure was moni- ored, 20 workers showing symptoms of VC illness after un- nown degrees of exposure, and 1 patient with VC-induced ngiosarcoma. Bone marrow cells from Chinese hamsters ex- osed to VC by inhalation (2,500 or 5,000 ppm for 4 hr/day 5) or ip injection (300 or 600 mg/kg/day x 5) were also nalyzed. The frequency of chromosome aberrations was not ncreased relative to controls in the exposed workers with no igns of VC illness. The frequency of aberrant metaphases in he workers with VC illness was 5.2% excluding gaps and 1.2% including gaps; these values were significantly higher han the control values of 2.1% and 5.5%, respectively. The ate of aberrant metaphases in the angiosarcoma patient was .3% excluding gaps and isogaps and 16.6% including gaps nd isogaps. The frequency of structural abnormalities in the C-treated hamster cells was also significantly higher than hat in the control cells, inclusive and exclusive of gaps. (15 efs.)

8-3071 **Irreversible Binding of Chlorinated Ethylenes to Macromolecules.** (Eng) Bolt, H. M. (Inst. oxicology, Univ. Tubingen, Wilhelmstrasse 56, D-7400 Tu- ingen-1, W. Germany); Filser, J. G. *Environ Health Perspect* 1: 107-112; 1977.

he binding of vinyl chloride (VC) and trichloroethylene TCE) to male Wistar rat macromolecules was investigated nd compared to that of carbon tetrachloride (CCl_4). Satura- ion of the rat metabolizing systems was achieved at 250 ppm C, 150 ppm TCE, and 250 ppm CCl_4. Data on the uptake f the compounds, the urinary excretion of metabolites, and xhalation after exposure indicated that the chlorinated ethy- enes were metabolized much faster than CCl_4. The metabo- ites of all three compounds bound irreversibly to tissue pro- eins, mainly in the liver. Other sites of binding included the idneys, small intestine, lung, and spleen. Irreversible binding of these compounds ranged within the same order of magnitude when related to the amount of the compound that had been absorbed. No differences in the relative portion of irreversibly bound metabolites were found after exposure of the rats to different atmospheric concentrations of the three compounds. In vitro studies indicated that TCE metabolism by rat liver microsomes in the presence of an NADPH-regenerating system leads to irreversible protein binding, mainly to albumin; similar findings have been reported for VC. Unlike VC, however, TCE metabolites also bind to non-SH proteins such as γ-globulin and concanavalin A. Thus, TCE metabolites irreversibly bind not only to SH groups of a protein, but also to NH_2 groups. (28 refs)

78-3072 **Mutagenicity of the Halogenated Olefin, 2-Bromo-2-chloro-1,1-difluoroethylene, a Presumed Metabolite of the Inhalation Anesthetic Halothane.** (Eng) Garro, A. J. (Dept. Microbiology, Mount Sinai Sch. Medicine, City Univ. New York, New York, NY, 10029); Phillips, R. A. *Mutat Res* 54(1): 17-22; 1978.

The mutagenicity of 2-bromo-2-chloro-1,1-difluoroethylene (BCD), a presumed urinary metabolite of halothane, was tested in the *Salmonella typhimurium* auxotroph reversion assay and in an assay in which a transformable strain of *Bacillus subtilis* was used to score the formation of mutagenic lesions produced by interaction of BCD with isolated transforming DNA. BCD induced both base-substitution and frameshift mutations reverting Salmonella strains TA92, TA98, and TA100. Since these are R factor-carrying strains, the induction of both types of mutations may be the results of error-prone repair of BCD-damaged DNA. Toxicity and mutagenicity were increased concomitantly at higher concentrations (10^{-3}-10^{-1} M), which may reflect BCD-mediated damage to cellular membranes, resulting in increased permeability. In the *B. subtilis* assay, there was a dose-dependent increase in the number of asporagenous mutants among the cells transformed to rifampin resistance with BCD-treated DNA. Inactivation of transforming activity also was observed, but it is not known whether the two effects are due to the same type of lesion in the DNA. Microsomal activation was not required for mutagenesis in either assay. The mutagenicity of BCD may result from direct reaction with nucleophilic sites on DNA bases. The biological significance of BCD mutagenicity with respect to the morbidities noted in epidemiological surveys of anesthesia personnel is not known. A note added in proof states that the BCD was actually only 63% pure; repetition of the experiments revealed that in the *Salmonella* assay, 99% pure BCD induced histidine-independent revertants, but only at toxic concentrations. (26 refs)

78-3073 **Butadiene Diepoxide Activation of Guanylate Cyclase.** (Eng) Vesely, D. L. (Div. Endocrinology and Metabolism, Dept. Medicine, Univ. Miami Sch. Medicine, Miami, FL, 33152); Levey, G. S. *Enzyme* 23(2): 140-143; 1978.

The effect of butadiene diepoxide (BD) on guanylate cyclase activity in various male Sprague-Dawley rat tissues was determined in vitro. BD markedly increased guanylate cyclase activity in all tissues tested, with the degree of stimulation ranging from 2- to 17-fold. The resultant increases in cyclic 3′,5′-guanosine monophosphate secondary to guanylate cyclase activation were significant in all tissues. In terms of max responsiveness to BD in vitro: bladder > kidney > heart > liver > spleen > stomach > pancreas > colon. Max stimulation of hepatic guanylate cyclase was found at a concentration of 100 millimole(mmol)/liter (20-fold increase); a 5-fold increase was noted at 1 mmol/liter and no significant increase at 0.1 mmol/liter. The precise mechanism of guanylate cyclase activation is not understood. (20 refs)

78-3074 **Mutagenic Interaction of Caffeine on Ethyleneimine-induced Chromosomal Damage in a Reconstructed Karyotype of Barley.** (Eng) Gecheff, K. I. (Inst. Genetics and Plant Breeding, Sofia 1113, Bulgaria). *Mutat Res* 50(1): 77-83; 1978.

The effect of caffeine (CF: 5 x 10^{-3} M for 75 min) on the intrachromosomal distribution of ethyleneimine (EI)-induced aberrations was studied in resting (dry) seeds of the barley translocation line T-1586. EI alone (0.04% for 75 min) increased the spontaneous aberration frequency markedly (up to 0.01/cell). The aberrations included isochromatid breaks, duplication deletions, intercalary deletions, chromatid translocations, and triradials. With the dry seeds, the peak of the aberration-frequency curve typical for the mutagens with ‘delayed’ action was not clearly pronounced. CF enhanced the frequency of chromosome aberrations by a factor of 6.2 when applied immediately after EI treatment. The results indicate that CF exerts an effect on the cells long before the beginning of DNA synthesis. CF specifically influenced the distribution pattern of EI-induced aberrations in that it decreased the relative frequencies of centromeric aberrations. Some segments (15, 18, 20, 42, 50, and, especially, 30 and 53) showed a greater sensitivity to the CF enhancement of EI-induced damage. Also, certain chromosome segments revealed a specific involvement in certain types of aberration. It is possible that the capacity of the centromere regions to be involved in aberration formation is restricted during CF enhancement of EI-induced damage. (14 refs)

78-3075 **Enhancement by Caffeine of Sister-Chromatid Exchange Frequency in Lymphocytes from Normal Subjects after Treatment by Mutagens.** (Eng) Faed, M. J. (Cytogenetics Lab., Univ. Dept. Pathology, Ninewells Hosp. and Medical Sch., Dundee, DD2 1UB); Mourelatos, D. *Mutat Res* 49(3): 437-440; 1978.

A study was made of the enhancing effect of caffeine on sister chromatid exchange (SCE) frequency in mutagen-treated lymphocytes from normal subjects. Phytohemagglutinin (PHA)-stimulated cultures of whole blood were grown in the presence of 12 μM bromodeoxyuridine (BUdR). 8-Methoxypsoralen (8-MOP) and UV-A (0.74 joule/cm^2) were administered prior to the addition of PHA and BUdR, but all other agents tested and caffeine were given with the BUdR at 18 hr after culture initiation. Caffeine (5 x 10^{-4}) induced a small but significant increase in SCE rates. However, when caffeine was added to cultures exposed to mitomycin C, 8-MOP/UV-A, 4-nitroquinoline 1-oxide or trenimon, at doses that induce SCE, the effect of the caffeine was synergistic. N-Methyl-N′-nitro-N-nitrosoguanidine (MNNG: 6.6 x 10^{-5} M) had a small effect on SCE rates, but further increases in concentration to 10^{-3} M had no further effect. Post treatment of MNNG-treated cultures with caffeine was also without effect. The effect of posttreatment with caffeine on SCE rates in human lymphocytes following treatment with mutagens is the reverse of that reported for cultured rodent cells. It is suggested that the effect of caffeine on SCE levels in any particular cell type may be determined by the proportion of responsibility for repair carried by excision or postreplication mechanisms. (19 refs)

78-3076 **The Inhibitory Effect of Cysteine on the Mutagenic Activities of Several Carcinogens.** (Eng) Rosin, M. P. (Cancer Res. Centre, Univ. British Columbia, Vancouver, British Columbia, Canada V6T 1W5); Stich, H. F. *Mutat Res* 54(1): 73-81; 1978.

The Salmonella/microsome mutagenesis assay was used to determine the effect of the reducing agent cysteine (α-amino-β-mercaptopropionic acid) on the mutagenicity of several carcinogens: N-methyl -N′- nitro -N- nitrosoguanidine (MNNG), N-acetoxy -2- acetylaminofluorene, N-hydroxy-2-acetylaminofluorene, 4-nitroquinoline 1-oxide methyl methanesulfonate, 5-nitro-2-furaldehyde semicarbazone (nitrofurazone, NF), 2-(2-furyl) -3- (5-nitro -2-furyl)acrylamide, aflatoxin B_1 and the nitrosation products of methylurea and methylguanidine. *Salmonella typhimurium* strains TA98, TA100, and TA1535 were used. At 2.5-10 mM, cysteine inhibited the mutagenic effects of MNNG and the methylguanidine nitrosation products completely; the mutagenicity of all the remaining compounds except NF was inhibited to various extents. Cysteine concentrations of 20-200 mM were required to inhibit NF-induced mutagenesis. The extent of inhibition varied with the particular carcinogen assayed and with the doses of cysteine and carcinogen. It is theorized that reducing agents could act as nucleophiles competing with nucleophilic sites on DNA for the electrophilic ultimate mutagen. Thus, the mutagenic potency of a compound may be related to the rate at which its active radicals are formed and to their electrophilic strength. An increase in these variables would increase he mutagenic potency of a compound as well as the amount f trapping agent required to inhibit its mutagenicity. Other heories are also proposed. (34 refs)

8-3077 **Carcinogenicity of Flower Stalks of *Petasites japonicus* Maxim. in Mice and Syrian Golden amsters.** (Eng) Fushimi, K. (Dept. Pathology, Gifu Univ. ch. Medicine, Gifu-City 500, Japan); Kato, K.; Kato, T.; atsubara, N. *Toxicol Lett* 1(5/6): 291-294; 1978.

he carcinogenicity of the yellow flower stalks of *Petasites aponicus* Maxim. was investigated in ddN, Swiss, and 57BL/6 mice and Syrian golden hamsters. The flower stalks ere dried, milled, and mixed with a basal diet to a concenration of 4%. The animals were placed on the diet for 480 ays. Animals were autopsied at death or when sacrificed ecause of a moribund condition, or at the termination of the xperiment. Of 45 ddN mice, 1 had a hemangioendothelial arcoma of the liver, 4 had reticulum cell neoplasms of the iver, 24 had pulmonary adenomas, 6 had adenocarcinomas f the lung, and 3 had other miscellaneous tumors. No signifiant tumor incidence was noted in any of the other animals tudied. However, proliferative changes in the bile duct, bile uct epithelium, and sinusoidal endothelium of the liver were bserved in all animals, particularly in the C57BL/6 ice and the hamsters. The species and strain difference n susceptibility to the carcinogenicity of these flower talks may be due to differences in ability to metabolize he carcinogenic alkaloid petasitenine in the liver. 8 refs)

8-3078 **Expression of a Bacterial Gene Turned on by a Potent Carcinogen.** (Eng) Levine, A. (Section e Radiobiologie Cellulaire, Laboratoire d'Enzymologie, .N.R.S., 91190, Gif-sur-Yvette, France); Moreau, P. L.; edgwick, S. G.; Devoret, R.; Adhya, S.; Gottesman, M.; as, A. *Mutat Res* 50(1): 29-35; 1978.

method is described whereby a potential carcinogen can e detected within 2 hr by measuring the induction of galacokinase synthesis. A strain of *Escherichia coli* K12 s used in which the galactose operon is integrated nto an early transcribed region of prophage λ and is hus directly under the negative control of the λ reressor. Activated aflatoxin B_1 (AFB_1) induced galactoinase synthesis in the tester strain SA 1512, whereas ure AFB_1 alone did not. A linear dose-response curve as obtained between 0.5 and 25 μg/ml of activated FB_1, enzyme production being enhanced about 0 times over background levels by 25 μg/ml. Using tester train SA 1511, which is similar to SA 1512 but carries a utant gene (*cI857*) that directs the synthesis of a thermolaile repressor, the amount of galactokinase produced at 42 declined at AFB_1 concentrations > 10 μg/ml. This showed the toxic effect of AFB_1 metabolites on the cells. The synthesis of galactokinase was not induced at 32 C by 25 μg/ml of AFB_1 because the λ*cI857* repressor was not inactivated at that temperature. (28 refs)

78-3079 **Aflatoxin Detected by Fluorescence Microscopy During Experimental Hepatocarcinogenesis in Rats and in Primary Hepatomas in Inhabitants of Zaire.** (Fre) Stora, C. (Faculte de Medecine de Nice, Chemin de Vallombrose, 06034 Nice Cedex, France). *Bull Acad Natl Med* 162(4): 287-291; 1978.

Female Sprague-Dawley rats were fed a normal diet or a diet containing 1 or 5 ppm aflatoxin B_1 (AFB_1), or they were inoculated ip with 1 μg of AFB_1 while on a normal diet. Animals were killed every 2 days for 20 days, and their organs were examined for the mycotoxin by immunofluorescence microscopy. Also, biopsy specimens of the livers of Zairians with hepatocarcinomas or cholangiomas who were known to have consumed food contaminated with aspergillus flavus were examined for AFB_1. All of the AFB_1-treated rats had evidence of the mycotoxin in the liver and in all organs beginning on the second day of examination. Initially, the AFB_1 was found only in the cytoplasm of the hepatocytes, but on days 6-15, immunofluorescence was observed in the nucleus. The nuclei of glands such as the maxillary and adrenal glands also contained AFB_1. In the human hepatocarcinoma biopsy specimens, healthy tissue surrounding the tumor showed intense AFB_1 immunofluorescence. The tumor was also very fluorescent, particularly the nuclei. The cholangiomas were much less fluorescent than the hepatocarcinomas, and there was evidence of aflatoxin G as well. (no refs)

78-3080 **Metabolic Activation of Aflatoxins Related to Their Mutagenicity.** (Eng) Gurtoo, H. L. (Dept. Experimental Therapeutics, Roswell Park Memorial Inst., New York State Dept. Health, Buffalo, NY, 14263); Dahms, R. P.; Paigen, B. *Biochem Biophys Res Commun* 81(3): 965-972; 1978.

Rat hepatic microsome-mediated DNA binding and mutagenesis to *Salmonella typhimurium* strain TA 100 by various aflatoxins and some mixed-function oxygenase (MFO)-mediated metabolites of aflatoxin B_1 (AFB_1) were studied. Hepatic microsomes isolated from 3-methylcholanthrene-treated C57BL/6J mice were used to prepare AFM_1, and hepatic microsomes from phenobarbital-treated rats and mice were used to prepare AFQ_1 and AFP_1, respectively. Hepatic microsomes from phenobarbital-treated rats were used in both the DNA-binding assay and the mutagenesis assay. In the range 28-112 μM, the DNA-binding activity of AFB_1 was linear with the substrate concentration. AFB_1 was shown to be a potent mutagen. AFB_2, a congener of AFB_1, that lacks the C_2-C_3 double bond, did not bind to DNA and was $< 1\%$ as mutagenic as AFB_1. AFG_1 was 18% as active as AFB_1 in the DNA-binding assay and 8%-10% as potent in the mutagenesis assay. AFG_2, a congener of AFG_1 that lacks the C_2-C_3 double bond, was inactive in binding to DNA and was as weak as AFB_2 in the mutagenesis assay. These data suggest that there is a good correlation between in vitro DNA binding and mutagenesis and that the critical site in the molecule is the C_2-C_3 double bond. In microsome-mediated DNA binding and mutagenesis to *S. typhimurium* TA100, AFM_1, AFQ_1, and AFP_1, were $< 50\%$ as active as AFB_1, indicating that MFO-mediated metabolism at sites other than the C_2-C_3 double bond in the AFB_1 molecule represents a deactivation step. (30 refs)

78-3081 **Quantitative Determination of Aflatoxins B_1, B_2, G_1, and G_2 in Foods.** (Ger) Muller, H. (Institut fur Forschung und Entwicklung, Maizena Gesellschaft mbH, Knorstrasse 1, D-7100 Helbronn, W. Germany); Siepe, V. *Dtsch Lebensm Rundsch* 4: 133-136; 1978.

A chromatographic-spectrophotometric method using methylene chloride as the extraction agent and solvent instead of chloroform, a suspect carcinogen, was developed for the determination of aflatoxins in foods. The aflatoxin B_1, B_2, G_1, and G_2 levels found in peanuts, hazelnuts, almonds, oat, rice, buckwheat, and wheat, barley, and corn products ranged from 75 to 108 ppb. (5 refs)

78-3082 **High Pressure Liquid Chromatographic Determination of Aflatoxins in Peanut Products.** (Eng) Pons, W. A. (U.S. Dept. Agriculture, Science and Education Admin., Southern Regional Res. Center, New Orleans, LA, 70179); Franz, A. O. *J Assoc Off Anal Chem* 61(4): 793-800; 1978.

A rapid, precise, and sensitive high-pressure liquid chromatographic method for determining aflatoxins in all types of peanut products is based on acidified aqueous methanol extraction, partition of aflatoxins into dichloromethane, and purification of the extract on silica gel. Accurate and sensitive detection of aflatoxins B_1, B_2, G_1, and G_2 was made at levels as low as 0.3-1.0 μg/kg. (18 refs)

78-3083 **Morphology, Growth and Activation of Chemical Carcinogens by Liver Cells in Culture (Meeting Abstract).** (Eng) Tompa, A. (Eppley Inst. Res. Cancer, Omaha, NB, 68105); Freed, H.; Huberman, E.; Langenbach, R. *In Vitro* 14(4): 337; 1978. (no refs)

78-3084 **Uptake of [^{14}C]-Aflatoxin B_1 by Liver and Kidney Slices of Different Animal Species.** (Eng) Prasanna, H. R. (Dept. Biochemistry, Vallabhbhaipatel Chest Inst., Univ. Delhi, Delhi-110007, India); Gupta, S. R.; Viswanathan, L.; Venkitasubramanian, T. A. *Z Lebensm Unters Forsch* 166(3): 162-163; 1978.

The respective uptake of [^{14}C]-aflatoxin B_1 (AFB_1) by liver and kidney slices of different animal species was compared. For rat, mouse, guinea pig, rabbit, and monkey, the uptake (cpm/100 mg tissue) in liver and kidney slices was 641 and 612, 598 and 561, 653 and 992, 398 and 682, and 882 and 735, respectively; while the LD_{50} (mg/kg) was 7.0, 60.0, 1.0, 0.5 and 2.2, respectively. Thus, the transport of the toxin into liver or kidney is not the major cause for the variation in species susceptibility to AFB_1. (10 refs)

78-3085 **7,8-Benzoflavone Stimulates the Metabolic Activation of Aflatoxin B_1 to Mutagens by Human Liver.** (Eng) Buening, M. K. (Dept. Biochemistry and Drug Metabolism, Hoffmann-LaRoche Inc., Nutley, NJ, 07110); Fortner, J. G.; Kappas, A.; Conney, A. H. *Biochem Biophys Res Commun* 82(1): 348-355; 1978.

The addition of 7,8-benzoflavone (7,8-BF) to a monooxygenase system from human liver markedly stimulated the metabolic activation of aflatoxin B_1 (AFB_1) to reactive intermediates that caused mutations in *Salmonella typhimurium* strains TA98 and TA100. When 5×10^{-5} M 7,8-BF was added to this monooxygenase system, the amount of AFB_1 needed for a mutagenic response was decreased by twenty- to fortyfold. 7,8-BF did not enhance the metabolic activation of AFB_1 to mutagens when rat liver was used as the source of monooxygenase. The results suggest that 7,8-BF may promote the formation of the carcinogenic metabolite AFB_1-2,3-oxide in human liver. (21 refs)

78-3086 **Nasopharyngeal Carcinoma Associated with Long-Term Arsenic Ingestion.** (Eng) Prystowsky, S. D. (Letterman Army Inst. Res., San Francisco, CA); Elfenbein, G. J.; Lamberg, S. I. *Arch Dermatol* 114(4): 602-603; 1978.

A 41-yr-old white woman with psoriasis who had been treated with Fowler's soln (potassium arsenite) for > 20 yr developed a metastatic nasopharyngeal carcinoma (NPC). Laboratory analysis indicated a serum antibody titer of 1:400 to Epstein-Barr virus. Palmar and plantar keratoses were present. Although the role of the virus in the development of this cancer cannot be excluded, it is suggested that NPC may be associated with long-term arsenic treatment in patients who are not genetically predisposed or residing in endemic regions the world. Long-term arsenic ingestion may be additive or nergetic with other causal factors in oncogenesis. (24 refs)

3-3087 **Cadmium Content of Lung, Liver and Kidney in Rats Exposed to Cadmium Oxide Fumes.** (Eng) oisset, M. (I.N.S.E.R.M. U. 122--Laboratoire de Toxicolo-ie, U.E.R. des Sciences Pharmaceutiques et Biologiques, ue J.B. Clement, F-92290 Chatenay-Malabry, France); Gi-ırd, F.; Godin, J.; Boudene, C. *Int Arch Occup Environ lealth* 41(1): 41-53; 1978.

Iale Sprague-Dawley rats were exposed to air containing .43 mg/m^3 cadmium oxide 30 min/day for 5 consecutive ays and then sacrificed at various times over a 3-mo period) determine the effects on the lungs, liver, and kidneys. The me-course effect on the relative wt of the lungs was biphasic, ith an increase noted immediately after exposure and again om days 42 to 56. Macroscopic examination of the pulmo-ary lobes of exposed rats sacrificed on days 42, 56, and 84 evealed areas of scar formation. Liver wt increased after 14 ays, but the increase was significant only when it was ex-ressed as percent of body wt. A second significant rise was bserved during the third month of observation. Little effect n kidney wt was noted except for a slight increase after 14 ays. Cd deposits in the lungs were cleared slowly, and the stimated half-life was 56 days. There was also a slight but ignificant accumulation of Cd in the liver that reached a max fter 2 mo. Cd concentrations in the liver never exceeded 0.63 ıg/g. Significant amounts of Cd accumulated in the kidney, ut only during the first month of observation. No mortality vas noted in the exposed groups. The body wt of exposed rats lecreased during the first 2 wk postexposure but then re-urned to normal. The slow clearance rate could be the result f impaired phagocytic ability of the pulmonary macro-hages. (35 refs)

'8-3088 **Cytotoxic Effects of Hexavalent and Trivalent Chromium on Mammalian Cells In Vitro.** (Eng) Levis, A. G. (Inst. Animal Biology, Univ. Padova, Via Lore-dan n. 10, 35100 Padua, Italy); Bianchi, V.; Tamino, G.; Pegoraro, B. *Br J Cancer* 37(3): 386-396; 1978.

The cytotoxic effects of potassium dichromate ($K_2Cr_2O_7$; hex-avalent Cr) and chromium chloride ($CrCl_3$; trivalent Cr) on cultured BHK 21 hamster fibroblasts and HEp 2 human epi-theliallike cells were determined. $K_2Cr_2O_7$ (10^{-5} to 10^{-3} M) stimulated the uptake of labeled thymidine (TdR) into the soluble intracellular pool, but Cr^{3+} (10^{-2} M) exerted an in-hibitory action. DNA synthesis was inhibited by treatment with both chromium compounds, but especially by $K_2Cr_2O_7$. Furthermore, 10^{-2} M $CrCl_3$ reduced the sensitivity of DNA and RNA to hydrolysis with per-chloric acid. Treatment of the cells with $K_2Cr_2O_7$ in balanced salt soln, in which Cr^{6+} reduction is less marked, induced more pronounced cytotoxic effects than treatments in complete growth medium. HEp cells were more sensitive to hexavalent Cr than BHK fibroblasts: in the former line, TdR uptake was less stimulated, and DNA synthesis and cell survival were more affected. Survival of BHK cells to $K_2Cr_2O_7$ indicated a multihit mechanism of cell inactivation, with about 10 independent Cr-induced events being necessary for cell death. The cytotoxic effects of Cr were attributed to the action of Cr^{6+} at the plasma membrane level on the mechanisms involved in nucleoside uptake and to the interaction of Cr^{3+} at the intracellular level with nucleophilic targets on the DNA molecule. (36 refs)

78-3089 **Bronchopulmonary Carcinomas in Two Chromium-exposed Workers Employed in the Same Section of an Electroplating Factory.** (Fre) Michel-Briand, C. (Inspection medicale du travail, 23, rue de la Republique, 25000 Besancon, France); Simonin, M. *Arch Mal Prof* 38(12): 1001-1013; 1977.

Bronchopulmonary carcinoma occurred in two men (41 and 47 yr old) employed in the same electroplating section of a factory. One patient was exposed to toxic chromium vapors for 9 yr, and the second was exposed to chromic acid for > 5 yr; both men had a history of smoking. Changes in the working conditions had increased the risk over the years. It is hypothesized that these two carcinomas were related to the inhalation of chromic acid. (22 refs)

78-3090 **In Situ Mutagenic and Other Effects Associated with Lead Smelting.** (Eng) Lower, W. R. (Dept. Family and Community Medicine, Environmental Trace Substances Res. Center, Columbia, MO, 65201); Rose, P. S.; Drobney, V. K. *Mutat Res* 54(1): 83-93; 1978.

The applicability of several plant systems, Zea (corn), Tradescantia (Trad: spiderwort), and Glycine (soybean), to in situ mutagenesis monitoring was tested; the mutagenic impact on the environment of a large lead-smelting operation in Southeastern Missouri, whose major effluents are Pb, Cd, Cu, Zn, and S, was assessed; and biochemical and physiological tests were used to determine any nonmutagenic toxicity to indigenous mammals and test plants. The latter included assays of Hb synthesis in Peromyscus (white-footed mouse), N fixation of Glycine root tissue and determination of Zea height, Zea pollen abortion, and day of first flowering of Trad. The total concentration of metals in the soil decreased with distance from the smelter. Levels of plant-available concentrations of Pb, Cd, Cu, and Zn were lower than the total metal levels, but the arithmetic correlations between the two were high. Mutation frequency and pollen abortion increased in Zea and Trad, and urinary δ-aminolevulinic acid excretion increased in the mice. Zea height, Trad flowering time, and Glycine root N fixation decreased. The change in the germinal mutation frequency of Zea and the somatic mutation frequency of Trad was not a linear function of distance from the smelter. The highest frequencies were at 1.7 km and not at 0.3 m. Greenhouse experiments using soil from these sites confirmed the findings that more moderate exposure can result in an increase in mutation frequency. However, with all five toxicity parameters, the most toxic conditions were at 0.3 km compared with the other sites (to 14.7 km) and control sites. This same level of toxicity and the resulting physiological damage may differentially mask mutagenesis at 0.3 km in Zea and Trad. Evidence is given that shows that the smelter operation, the only industry in an otherwise undeveloped area, was responsible for these effects. (21 refs)

78-3091 **Investigation of Exposure to Nickel and Lung Cancer Mortality: Case Control Study at Aircraft Engine Factory.** (Eng) Bernacki, E. J. (Dept. Lab. Medicine, Univ. Connecticut Sch. Medicine, Farmington, CT, 06032); Parsons, G. E.; Sunderman, F. W. *Ann Clin Lab Sci* 8(3): 190-194; 1978.

A case-control mortality study was performed at an aircraft engine factory to assess the possible association between exposure to nickel-containing compounds and death from lung cancer. Forty-two nonsalaried male workers who died of lung cancer from 1966 to 1976 were identified from a chronological registry of death certificates maintained by the company's medical department. Each of the decedents was matched with the next two nonsalaried decedents in the registry who were of the same sex and comparable age (±10 yr) and who died of causes other than cancer. Without knowledge of the workmen's identities or causes of death, one of the authors classified the deceased workmen as exposed or not exposed to nickel compounds during their employment. The proportion of workmen who died of lung cancer and were exposed to nickel (11/42) was equal to the proportion of workmen who died of noncancerous causes and were exposed to nickel (22/84). The results indicate that chronic occupational exposure to low atmospheric concentrations of nickel compounds did not increase the relative risk of mortality from lung cancer prior to retirement. (21 refs)

78-3092 **Microbiological Mutagenicity Studies of Pesticides In Vitro.** (Eng) Carere, A. (Istituto Superiore di Sanita, Rome, Italy); Ortali, V. A.; Cardamone, G.; Torracca, A. M.; Raschetti, R. *Mutat Res* 57(3): 277-286; 1978.

The mutagenic activity of 14 pesticides as pure compounds was compared in two in vitro microbial genetic assay systems. The pesticides were tested for the induction of point mutations in four strains of *Salmonella typhimurium* (TA1535, TA1536, TA1537, and TA1538) in the presence and absenc of rat liver microsome fractions and for the induction of resistance to low concentrations (3-5 $\mu g/ml$) of streptomyci in the filamentous bacterium *Streptomyces coelicolor*. In mos cases, the spot test technique was used: triangles of steril absorbent paper saturated with a soln of the test compoun were applied to the surface of the agar medium. The pesticides investigated were: aminotriazole, Benomyl, Captafol Captan, Dichlorvos, Dalapon-Na, Dinobuton, Dodine, Ioxynil, Mecoprop, Neburon, Picloram, Triallate, and Trichlorphon. In Salmonella, Captan and Triallate were mutageni for TA1535; Dichlorvos and Trichlorphon were negative i the spot test, but mutagenic after incubation in liquid culture of TA1535. In the *S. coelicolor* forward-mutation test, aminotriazole, Dichlorvos, Picloram, Trichlorphon, and Triallat were mutagenic in the spot test, and Captan showed weal mutagenicity with a plate incorporation technique. The results are compared with those in the literature. It is suggeste that the *S. coelicolor* test will prove useful for the study o environmental mutagens. (27 refs)

78-3093 **The Induction of II-III Translocations by Tris-(2,3-dibromopropyl) Phosphate in Drosophila.** (Eng) Berkowitz, S. (Dept. Zoology, Univ. Wisconsin Madison, WI, 53706). *Mutat Res* 57(3): 385-387; 1978.

The capacity of the flame retardant tris(2,3-dibromopropyl) phosphate (TBPP) to induce chromosome rearrangements was determined in Drosophila. Seven-day-old adult Canton-S males were fed for 48 hr on a 1.0% glucose soln containing 1,000 ppm (1.43 x 10^{-3} M) or 10,000 ppm (1.43 x 10^{-2} M) TBPP. Exposed males were mated immediately after treatment to brown ebony virgins in culture bottles containing 20 males and 40 females. Every 2 days, the males were provided with fresh vials of virgins to sample a variety of treated germ cell stages. F_1 males were singly mated in vial cultures to virgins, and F_2 cultures were scored for II-III translocations. The results showed that TBPP was capable of causing reciprocal translocations in Drosophila, with 8 translocations being found out of 8,000 tests. The translocation recovery at 10,000 ppm was not significantly different from that found at 1,000 ppm, a result that could be due to an enzyme saturation effect, as TBPP requires metabolic activation. The higher mutation rate found for early spermatids and/or spermatocytes relative to mature sperm is consistent with the view that these early stages are more mutable than later stages. (7 refs)

78-3094 **Mutagenicity of Derivatives of the Flame Retardant Tris(2,3-dibromopropyl) Phosphate: Halogenated Propanols.** (Eng) Carr, H. S. (Dept. Microbiology, New York Medical Coll., Valhalla, NY, 10595); Rosenkranz, H. S. *Mutat Res* 57(3): 381-384; 1978.

'he mutagenicity of some mono- and dihalopropanols, erivatives of the flame retardant tris(2,3-dibromopropyl) hosphate (TBPP), was tested in the *Salmonella typhimuri-* *m* assay. Both the bacteria and the chemicals were incor- orated into the agar overlay. Tester strains TA100, TA1535, 'A1538 were used in the presence and absence of metabolic ctivation (microsomal fraction derived from Araclor-in- uced rat livers). Specific mutagenicities (revertants/nano- iole) were calculated from the linear portion of the ose-response curve obtained with TA1535 in the absence of iicrosomal activation. All of the halogenated propanols test- d, except for 3-chloro-1-propanol, exhibited direct-acting ase-substitution activity, as evidenced by their mutagenicity or TA100 and TA1535 but not TZ1538. Even with microso- ial activation, 3-chloro-1-propanol remained genetically in- rt. All bromo analogs were more mutagenic than the corre- ponding chloro compounds except for the bromo analog of ,3-dichloro-1-propanol. The mutagenicity of some of the romine-containing chemicals was further increased in the resence of rat liver microsomes. (14 refs)

8-3095 **Present and Future Uses of Mutagenicity Tests for Assessment of the Safety of Food Additives.** Eng) Green, S. (Dept. Pharmacology, Howard Univ. Coll. ledicine, Washington, DC, 20059). *J Environ Pathol Toxicol* (2): 49-54; 1977.

'he tier approach to investigating the potential mutagenicity f food additives and substances generally recognized as safe GRAS substances) is described. This approach is used to set esting priorities. The first tier, which is a prescreen to deter- iine whether a chemical has the potential to cause genetic amage, is composed of tests using *Salmonella typhimurium* 'A1535, TA1537, TA1538, TA98, and TA100, with and vithout metabolic activation, for the detection of gene muta- ions. Tier 2 is used to confirm the mutagenic activity detect- d at tier 1 and is comprised of tests in mouse lymphoma .5178Y cells and in *Drosophila melanogaster* and the rat ominant lethal assay. Tier 3 attempts to define the genetic isk to humans that is associated with use of a substance onfirmed as a mutagen in tiers 1 and 2. The specific locus ssay and the heritable translocation test are used at tier 3. nformation assembled in 1974 from tests of 51 GRAS sub- tances was compared, and the results showed that there is ery little correlation among the short-term mutagenicity ests or between the short-term and animal tests. It is con- luded that mutagenicity tests in the future will probably be ised (1) as a prescreen for in vivo carcinogenicity studies and 2) as a means of identifying materials that may produce heri- able genetic damage in humans. (5 refs.)

'8-3096 **Chromosomal Damage and Hair Dyes (2 Letters to Editor).** (Eng) Kirkland, D. J. (British Indus- rial and Biological Res. Assoc., Carshalten, Surrey, England); Kirkland, D. J.; Lawler, S. D.; Venitt, S. *Lancet* 2(8083): 271-272; 1978.

Data from a previous study of the effects of hair dyes on chromosomes are interpreted to mean that women who dye their hair are unlikely to suffer greater chromosomal damage than women who have had recent exposure to x-rays or virus infection. In a response, the original authors state that the x-ray exposures referred to were high-dose diagnostic x-rays, and the virus exposures were recent influenza, chicken pox, heavy vaccination, or glandular fever. In fact, the data showed that there was a statistically significant excess of chromosomal damage (mainly chromatid breaks) in women with dyed hair. (no refs)

78-3097 A Mutation in *Drosophila melanogaster* that **Generates Ovarian Tumors After a Latent Period (Meeting Abstract).** (Eng) Gollin, S. M. (Northwestern Univ., Evanston, IL); King, R. C. *Genetics* 88(4, part 2, Suppl): s31-s32; 1978. (1 ref)

78-3098 **Carcinogenesis Studies on Organ Cultures of Animal and Human Respiratory Tissues.** (Eng) Saffiotti, U. (Experimental Pathology Branch, Carcinogenesis Res. Program, DCCP, NCI, NIH, Bethesda, MD, 20014); Harris, C. C. *In: Carcinogens: Identification and Mechanisms of Action. Proceedings of the Thirty-First Annual Symposium on Fundamental Cancer Research, held in Houston, Texas, 1-3 March 1978.* University of Texas System Cancer Center, M. D. Anderson Hospital and Tumor Institute. (Houston, Texas): pp. 2-4; 1978.

Organ culture models of respiratory tract carcinogenesis are described. Preneoplastic epithelial lesions induced by chemical carcinogens in cultured human bronchi were identifiable by light and electron microscopy. Autoradiography was used to identify the cellular localization of the bound carcinogens and to measure changes in the cell kinetics of the respiratory epithelium. In biochemical studies, procarcinogens (eg, polynuclear aromatic hydrocarbons, N-nitrosamines, and mycotoxins) were enzymatically activated by human tissues to electrophiles that formed adducts with DNA. Human tissue-mediated mutagenesis was demonstrated when human bronchi explants were cocultivated with Chinese hamster V-70 cells in the presence of procarcinogens. (no refs)

78-3099 **Unscheduled DNA Synthesis Testing of Pesticides (Meeting Abstract).** (Eng) Mitchell, A. D. (Stanford Res. Inst., Menlo Park, CA, 94025); Robinson, D.

E.; Sterling, G. P.; McAfee, P. A.; Waters, M. D. *Mutat Res* 53(1): 109; 1978. (no refs)

78-3100 Carcinogenic Activity of Compounds Eluting from Elastic Resins into Food. (Rus) Medvedev, V. I. (All-Union Res. Inst. Hygiene and Toxicology Pesticides, Polymers and Plastics, Kiev, USSR); Rodionov, G. A. *Vopr Onkol* 24(6): 94-99; 1978.

The potential carcinogenic activity of the compounds that can elute from elastic resins into food products was tested in C57BL mice. Extracts from two types of resins (I and II) were administered either intragastrically (0.024 and 0.068 μg/kg, respectively, 3x/wk, for 6 mo) or sc (0.2 μg/kg, 2x/wk, for 8 mo). The animals were sacrificed after 18 mo. Intragastric administration of resins I and II induced tumors in 11/46 and 3/37 mice, respectively. The tumors included pulmonary adenomas (5 and 2), papillomas of the cardiac stomach (2 and 1), and tumors of other location (lipoma of the small intestine, liver adenoma, and renal fibroma, which were detected only in mice exposed to type I). The sc application of type I resin induced tumors in 11/48 mice (6 skin papillomas, 4 pulmonary adenomas, and 1 adenocarcinoma of the stomach). (12 refs)

78-3101 Absence of Chromosome Damage in the Bone Marrow of Rats Fed Detergent Actives for 90 Days. (Eng) Hope, J. (Environmental Safety Div., Unilever Res. Lab., Colworth House, Shanbrook, Bedford, England). *Mutat Res* 56(1): 47-50; 1977.

Four detergent actives, sodium lauryl sulfate, DOBS 055 (nominally dodecyl benzene sulfonate, but with a chain length of 10-15 carbon atoms), Dobanol 25 sulfate LCU, and Dobanol 25 sulfate HCB, were tested for their potential to induce chromosome damage in vivo after chronic administration in the diet to rats. The detergent actives were fed to Colworth/Wistar rats for 90 days at the max tolerated dose, 1.13% active ingredient in each case. Sodium lauryl sulfate and DOBS 055 were also fed at 0.56%. Two hours before sacrifice, the rats were inoculated ip with colchicine. Chromosome preparations were made from the bone marrow and scored for the presence of rearrangements, chromatid gaps and breaks, and isochromatid gaps and breaks. The four detergent actives had no effect on the chromosomes of rat bone marrow cells. The absence of chromosome damage suggests that these detergent actives are harmless. (3 refs)

78-3102 Experiments on the Carcinogenic Effect of Ortho-Toluol-sulfonamid (OTS). (Eng) Schmahl, D. (Inst. Toxicology and Chemotherapy, German Canc Res. Center, Im Neuenheimer Feld 280, D-6900 Heidelber W. Germany). *Z Krebsforsch* 91(1): 19-22; 1978.

The carcinogenicity of O-toluenesulfonamide (OTS), an e sential impurity in saccharin prepared by the Remser Fahlberg method, was investigated in Sprague-Dawley rat The OTS was mixed with the food and fed to the rats at dail doses of 200 and 20 mg/kg; the diets were continue for life. The max dose given amounted to 17 g/kg. No life shortening effects were observed, and the incidence of malig nant tumors in the OTS-treated animals was identical to tha in a control group. However, one animal on the high-dos diet developed a urinary bladder carcinoma; four benign tu mors were noted in four other animals in this group. Thre animals in the low-dose group developed bladder papillomas Although these results do not prove that OTS is carcinogenic it is suggested that saccharin used in future experiments b kept as pure as possible. (8 refs)

78-3103 Analysis of Aryl Hydrocarbon Hydroxylase Ac tivity in Human Lung Tissue, Pulmonary Mac rophages, and Blood Lymphocytes. (Eng) McLemore, T. L (Dept. Medicine, Infectious Diseases Section, Baylor Coll Medicine, 1200 Moursund Ave., Houston, TX, 77030). *Cancer* 41(6): 2292-2300; 1978.

Aryl hydrocarbon hydroxylase (AHH) levels were measured in pulmonary alveolar macrophages (PAM) freshly lavaged from the lung, in fresh surgically excised lung tissue, and in cultured mitogen-stimulated peripheral blood lymphocytes Samples were obtained from seven patients without cancer (controls) and seven patients with untreated primary lung cancer; all were cigarette smokers. AHH levels in the PAM and lymphocytes from individual control patients, but not from individual lung cancer patients, were correlated positively. AHH levels in freshly excised lung tissue and in the PAM correlated strongly in the controls but only weakly in the cancer patients. AHH activity in freshly excised lung tissue was also positively correlated with AHH fold-induction ratios in cultured lymphocytes from individual controls; there was no such correlation in individual cancer patients. In the controls, but not in the cancer patients, there was an excellent positive correlation among AHH activity levels in fresh PAM and in fresh lung tissue and fold-induction of AHH in cultured lymphocytes. These data indicate that the capacity for AHH induction is similar in the fresh lung tissue, fresh PAM, and cultured mitogen-stimulated lymphocytes of cigarette smokers without evidence of lung cancer, but that AHH levels in similar tissues from individual lung cancer patients are not correlated positively. (42 refs)

78-3104 Aryl Hydrocarbon Hydroxylase Activity in Subpopulations of Peripheral Blood Mononu-

clear Cells. (Eng) Jett, J. R. (Dept. Pathology and Anatomy, Mayo Clinic/Foundation, Rochester, MN, 55901); Stobo, J. D.; Moses, H. L. *Cancer Res* 38(7): 1979-1982; 1978.

The activity of aryl hydrocarbon hydroxylase (AHH) was measured in peripheral blood mononuclear cell (PMC) subfractions consisting of T-cell-enriched, T-cell-depleted, and monocyte-depleted populations. Fluorometrically and radiometrically, the T-cell-enriched populations consistently showed enhanced AHH activity compared with the total PMC population. This enhanced activity was observed by the sheep RBC rosette method when the T-cell-enriched populations were isolated either before or after 96 hr of lymphocyte culture or by the nylon wool column technique before lymphocyte culture. T-cell-depleted populations (B-cell-enriched) obtained by the sheep RBC rosette method had diminished AHH activity. Monocytes were shown to contribute to the total PMC AHH activity through an indirect technique, in which monocytes were first depleted from PMC by the carbonyl iron method. The monocyte-depleted populations had less AHH activity than the total PMC population after both 24 and 96 hr of culture. The greatest amount of AHH activity was present in PMC populations with their native number of monocytes when cultured for 96 hr in the presence of mitogens. These results suggest that studies of AHH activity in patients with different cancers should take into account the relative composition of PMC and the degree of mitogen stimulation. (29 refs)

78-3105 **The Interaction of Asbestos Exposure and Smoking on Respiratory Health.** (Eng) Rossiter, C. E. (MRC Pneumoconiosis Unit, Llandough Hosp., Penarth, Glamorgan CF6 1XW, Wales); Berry, G. *Bull Eur Physiopathol Respir* 14(2): 197-204; 1978.

The association between asbestos exposure, smoking, and the development of asbestosis was investigated in workers at the Royal Navy Dockyards (RND) and in workers at an asbestos textile factory. The presence of small opacities on chest radiographs and crepitations that are not cleared on coughing were studied because of their importance in the diagnosis of asbestosis. A total of 195 asbestos workers and 1,005 other workers at the RND formed the basis for the first study. Among the asbestos workers who smoked, the prevalence of small opacities rose markedly for those with >20 yr exposure to asbestos; this finding did not hold for exsmokers and nonsmokers, who had prevalence rates compatible with a base rate of approx 3%. Crepitations that did not clear upon coughing also showed higher prevalence rates for smoking asbestos workers with >20 yr exposure to asbestos. Prevalence rates among exsmokers and nonsmokers did not vary significantly from the av of 8%. In the second study, the presence of crepitations and asbestosis was determined in nonsmokers, exsmokers, and people who smoked 1->25 cigarettes/day in the textile factory. The av cumulative exposure to asbestos was similar for all smokers. Crepitations were never heard in nonsmokers or in men who smoked <5 cigarettes/day; the prevalence in the heavier smokers averaged 19%. The presence of small opacities in the lung was also greater in heavier smokers than nonsmokers. These findings indicate that among asbestos workers, smokers have a higher risk of developing asbestosis than nonsmokers. A review of the pertinent literature suggested that a synergism between asbestos exposure and smoking occurs at an early age and can lead to premature death. (14 refs)

78-3106 **Pleuropulmonary Disease among Asbestos Workers in Relation to Smoking and Type of Exposure.** (Eng) Weiss, W. (Div. Occupational Medicine, Dept. Medicine, Hahnemann Medical Coll. and Hosp., 6401 New Coll. Building, 230 N. Broad St., Philadelphia, PA, 19102); Theodos, P. A. *J Occup Med* 20(5): 341-345; 1978.

The chest roentgenograms of employees aged 40+ in two asbestos manufacturing plants were read by consensus without knowledge of the plant or smoking habits. Plant A used only chrysotile asbestos throughout its history, Plant B used amosite as well as chrysotile, the amosite being limited to the period 1950-1964. The incidence of pulmonary disease was 10/40 in Plant A and 16/48 in Plant B. The incidence of pleural thickening was 18% in Plant A and 35% in Plant B. Neither age nor work duration were factors in these differences. In Plant A, there was no obvious relationship between smoking and pleuropulmonary disease. In Plant B, there was a definite relationship of smoking to pulmonary disease and perhaps to pleural thickening. Both types of asbestos and smoking habits appear to be determinants of pleuropulmonary disease in asbestos workers. (11 refs)

78-3107 **Differential Response in the Male and Female Tracheal Epithelium Following Exposure to Tobacco Smoke.** (Eng) Hayashi, M. (Thorndike Lab., Dept. Medicine, Harvard Medical Sch., Boston, MA); Sornberger, G. C.; Huber, G. L. *Chest* 73(4): 515-518; 1978.

Histochemical quantification of goblet cells and measurements of epithelial thickness were made in the trachea of male and female CD rats exposed for 30 consecutive days (3-10 min exposures/day) to fresh whole smoke from standard 2R1 Kentucky reference unfiltered cigarettes. Smoke exposure increased the total goblet cell count in both sexes, with the female rats differentially responding to a greater degree than the male rats. There was a shift from PAS-positive to alcian blue-positive goblet cells, an increase in the number of both 'large' and 'small' goblet cells, and an increase in epithelial thickness. PAS-positive 'small' cells, the major glycoprotein-reactive cell in the rat tracheal epithelium, increased in the female rats but showed no increase in the male rats.

However, male rats contained a substantially higher proportion of alcian blue-positive cells than did female rats, both before and after smoke exposure. It is not known whether these differences in the morphologic response of the tracheal epithelium to experimental exposures to smoke exist in humans and whether the differences contribute to the differential risk of respiratory disease following tobacco smoking in men and women. (24 refs)

78-3108 Smoking and Lung Cancer: A Cohort Data Study of Men and Women in England and Wales 1935-70. (Eng) Townsend, J. L. (Univ. Essex, Colchester, England). *J R Statist Soc A* 141(Part 1): 95-107; 1978.

In 1965, Pike and Doll postulated that the risk of death from lung cancer among doctors was linearly related to the level and duration of cigarette smoking. A generalization of the Doll and Pike model gave a very good approximation to male mortality from lung cancer over the period 1935-1970, and it explained 98.9% of the variation in excess mortality. The fit for women was not as close as that for men, but the model accounted for 93.8% of the variation between age groups and over time. The model predicted the fall in 1973 mortality rates in men aged 35-65 and the rise in mortality among women aged 45-80. In the period 1966-1970, smoking accounted for 94.4% of lung cancer mortality in men and 71.2% of the mortality in women. Cigarette smoking affected the mortality risk equally, whether the smoking took place early or late in life. Pipe and cigar smoking appeared to have an insignificant effect on mortality. (13 refs)

78-3109 Carboxyhaemoglobin Levels and Inhaling Habits in Cigarette Smokers. (Eng) Wald, N. (Dept. Regius Professor Medicine, Univ. Oxford, Radcliffe Infirmary, Oxford OX2 6HE, England); Idle, M.; Bailey, A. *Thorax* 33(2): 201-206; 1978.

Carboxyhemoglobin (COHb) levels were determined in 520 male cigarette smokers, aged 35-64 yr, and the results were compared with those obtained for 1,891 nonsmokers. The mean COHb was 0.7% among the nonsmokers and 5.3% among the smokers. The level among smokers that had not smoked on the day of the test was 1.1%. The mean COHb level, standardized for the number of cigarettes smoked before the test on the day of the test was 4.0% for self-described noninhalers, 5.2% for slight inhalers, 5.3% for moderate inhalers, and 5.6% for deep inhalers. The increasing trend in COHb levels with extent of inhalation was small but statistically significant. These findings indicate that smokers who say they do not inhale nearly always inhale enough smoke to cause their COHb level to be well above that seen in nonsmokers; and that there is a weak but statistically significant correlation noted between COHb levels and the self-described level of inhaling. They also may help to explain the epidemiolog cal findings that the risk of lung cancer is higher amon self-described noninhalers than nonsmokers and th the association between inhaling and lung cancer i cidence is weak among light smokers. (18 refs)

78-3110 Smoking, Chronic Bronchitis, Bronchiolar Obstruction, and Bronchial Carcinoma. (Ger Scherrer, L. (Pneumologische Abteilung, Medizinische Universitatsklinik, Inselspital, CH-3010 Bern, Switzerland Zeller, C.; Scherrer, M. *Schweiz Med Wochensch* 108(15): 556-559; 1978.

Correlation among smoking, chronic bronchitis, and bronchiolar obstruction were studied in 396 patients (mostly men aged 33-80 yr) with lung carcinoma. Chronic bronchitis (cough and expectoration for > 5 yr) was found in 221 patients (Group 1), but not in the remaining 175 patients (Group 2). The number of heavy (6-20 cigarettes/day) and very heavy (>20 cigarettes/day) smokers and of patients with severe bronchiolar obstruction was significantly higher in Group 1 than in Group 2 ($p < 0.0005$). For both groups combined, however, there was no correlation between the first-minute forced expiratory volume and smoking. In Group 1, patients with severe obstruction included light ($<$ 5 cigarettes/day), heavy, and very heavy smokers in about identical proportions. There were 123 heavy smokers in Group 1: 54 of them had severe bronchiolar obstruction, 69 light obstruction. There were 65 heavy smokers in Group 2: 7 of them had severe obstruction, 58 slight obstruction. The findings suggest that heavy and very heavy smoking for decades seems to protect certain lung cancer patients from chronic bronchitis and bronchiolar obstruction. (16 refs)

78-3111 Effect of a Nitrate Test Meal on Salivary and Gastric Nitrite Levels in Humans. (Fre) Klein, D. (Departemente de Nutrition et des Maladies Metaboliques, Universite de Nancy I, 40, rue Lionnois, 54 000 Nancy, France); Gaconnet, N.; Poullain, B.; Debry, G. *Food Cosmet Toxicol* 16(2): 111-115; 1978.

The effect of a test meal containing 112 mg sodium nitrate on the levels of salivary and gastric nitrite and nitrate was studied in 10 normal subjects (3 men, 7 women: av age 25 yr). The test meal contained 10 g glucose, 5 g corn oil, 10 g powdered milk, 2.2 g polyethylene glycol (PEG), and 25 mg sodium nitrate. Salivary nitrite and nitrate was measured at half hour intervals for 6 hr after ingestion of the meal. Five of the 10 subjects had their saliva aspirated to prevent its passage to the stomach. Gastric samples withdrawn by a sump pump were tested for nitrite and nitrate in both the aspirated and nonaspirated groups. The levels of salivary nitrite rose rapidly during the first half hour after the meal and then slowly attained a max that varied markedly among the bjects. The max level of salivary nitrate was reached 1 hr ter the test meal; it declined thereafter, but at 6 hr had not reached the premeal level. Gastric levels of trate decreased in both groups but the rate of de- ease was slower than that of the PEG (used as a arker of gastric emptying). Gastric nitrite concen- ations did not change in the aspirated group, but in e nonaspirated group they increased rapidly. The ow of salivary nitrite was not sufficient to explain this crease, which may have been due to nitrate reduction by al microflora during esophageal transit. (18 refs)

3-3112 **Mutagenic and Chromosome-Breaking Effects of Azide in Barley and Human Leukocytes.** Eng) Sander, C. (Dept. Plant Pathology, Washington State Jniv., Pullman, WA, 99164); Nilan, R. A.; Kleinhofs, A.; ig, B. K. *Mutat Res* 50(1): 67-75; 1978.

xtensive chromosome analyses in barley were conducted to etermine whether azide mutagenicity could be increased by ncreasing the germination time before mutagen treatment. n addition, a preliminary analysis of the effect of azide on uman WBC chromosomes was made. Azide-induced M_2 arley seedling mutations increased with increasing germina- ion time prior to treatment up to a max mutation frequency t 8 hr (75%) and 16 hr (78%) on a percent mutant events asis or 12 hr (19.7%) on a percent mutant seedling basis. he peak of seedling mutations suggested an azide-sensitive tage between 8 and 16 hr germination. Azide-induced em- ryo lethality and/or ovule sterility, as measured by M_2 seedlings per M_1 spike, increased up to 12 hr and hen decreased with increasing germination. Azide did ot increase the frequencies of chromosome aberrations, centric fragments, or dicentric chromosomes in em- ryonic barley shoots pregerminated for 8 or 12 hr, nicrospores of barley, or human WBC obtained from ormal volunteers. Although azide did have an effect n the general morphology of the human chromosomes, t may have been a physiologic rather than a genetic ffect. The results suggest that azide may act only on eplicating DNA and that it may act only as a point- nutation mutagen. (21 refs)

8-3113 **Effects of Carcinogens on Nuclear Protein Composition and Metabolism. Alterations in Chromatin Structure and Activity as Related to Postsynthet- c Modification of Histones and to Dispositions of DNA-Binding Proteins.** (Eng) Allfrey, V. G. (Rockefeller Jniv., New York, NY); Boffa, L. C.; Vidali, G. *In: Carcinogens: Identification and Mechanisms of Action. Proceedings of the Thirty-First Annual Symposium on Fundamental Cancer Research Held at Houston, Texas, 1-3 March 1978.* University of Texas System Cancer Center, M. D. 78-3114 **The Toxicities and Mutagenic Properties of Ethylidene Gyromitrin and N-Methylhydrazine with *Escherichia coli* as Test Organism.** (Eng) Von Wright, A. (Food Res. Lab., Technical Res. Centre Finland, Biologinkuja 1, SF-02150 Espoo 15, Finland); Niskanen, A.; Pyysalo, H. *Mutat Res* 56(2): 105-110; 1977.

The toxicities and mutagenic properties of ethylidene gyromitrin (EG), the main poisonous substance of the false morel (*Gyromitra esculenta*), and N-methylhydrazine (NMH), the possible metabolic end product of EG, were studied using *Escherichia coli* as the test organism. NMH (20 μg) was strongly bacteriocidal, but EG showed no toxicity. In liquid culture, 3 μg NMH/ml nutrient broth caused growth inhibition; EG had no effect. Tests with repair-deficient strains indicated that they were more sensitive to NMH than repair-proficient strains. In revertant tests, NMH caused a dose-dependent increase in revertants at concentrations of 5-20 μg/ml. No increase in revertant frequency was noted at EG concentrations of up to 250 μg/ml. These results suggest that NMH could be responsible for the toxic effects of EG. (9 refs)

78-3115 **The Effect of Expression Time on the Frequency of Carcinogen-induced Mutants at the TK and HGPRT Loci in L5178Y Mouse Lymphoma Cells (Meeting Abstract).** (Eng) Brown, M. M. (Univ. North Carolina, Chapel Hill, NC, 27514); Clive, D. *Mutat Res* 53(1): 116-117; 1978. (no refs)

78-3116 **Effect of Schedule of 1,2-Dimethylhydrazine Administration on Its Carcinogenicity.** (Rus) Pozharisskii, K. M. (N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Vokhmianin, V. N.; Kulakov, N. A.; Balanski, R. M.; Likhachev, A. Ia.; Pemrov, A. C., Shaposhnikov, Ia. D. *Biull Eksp Biol Med* 85(3): 337-340; 1978.

The effect of the schedule of 1,2-dimethylhydrazine (DMH) administration on its carcinogenicity was studied in random-bred albino rats. The animals were divided into three groups: Group 1 received daily sc injections of DMH (3 mg/kg/injection), Group 2 received DNH 1 x/wk (21 mg/kg/injection) and Group 3 received DMH 2 x/wk (42 mg/kg/injection). Animals in all three groups received approx equal total doses of DMH (528, 514, and 524 mg/kg, respectively). Mice from Group 1 developed tumors in the large intestine alone, but mice from Groups 2 and 3 developed multiple tumors in various segments of the intestine (the extent of tumor dissemination was less pronounced in Group 3). The cytochrome P450 level in the liver microsomes was decreased significantly in Group 1 (2.48 IU, compared to 5.32 IU in untreated controls and 5.1 IU in Group 2). (9 refs)

78-3117 **Inhibition of 1,2-Dimethylhydrazine-induced Neoplasia of the Large Intestine in Female CF$_1$ Mice by Carbon Disulfide: Brief Communication.** (Eng) Wattenberg, L. W. (Dept. Laboratory Medicine and Pathology, Medical Sch., Univ. Minnesota, Box 609, Mayo Memorial Building, Minneapolis, MN, 55455); Fiala, E. S. *J Natl Cancer Inst* 60(6): 1515-1517; 1978.

The effect of carbon disulfide (CS$_2$) on 1,2-dimethylhydrazine (DMH)-induced carcinogenesis was studied in female CF$_1$ mice. Mice were given either 5.0 or 2.5 mg CS$_2$ in corn oil or corn oil only by gastric intubation. A fourth group did not receive anything at this time. Four hours later, all mice received 0.4 mg DMH sc. This dose was repeated at 1-wk intervals for 16 wk, except that upon the last eight administrations, the dose was increased to 0.6 mg. The experiment was ended 40 wk after the first DMH dose. Of 20 mice that had received DMH only, half had tumors of the large intestine or anus. Of 19 that had received the corn oil plus DMH, 10 had tumors of the large intestine and anus. In contrast, none of the 20 given 2.5 mg CS$_2$ + DMH and none of the 19 given 5.0 mg CS$_2$ + DMH had large intestinal or anal tumors. These results indicate that CS$_2$ inhibits DMH-induced tumors of the large intestine and anus. (14 refs)

78-3118 **Formylhydrazine Carcinogenesis in Mice.** (Eng) Toth, B. (Eppley Inst. Res. in Cancer, Univ. Nebraska Medical Center, Omaha, NB, 68105). *Br J Cancer* 37(6): 960-964; 1978.

The tumorigenicity of formylhydrazine (FH) was studied in Swiss mice who were given 0.125% FH in their drinking water for life beginning at 6 wk of age. Compared with untreated controls, survival was shortened significantly in the treated mice. Of the treated females, 47 (94%) developed 531 lung tumors: 149 adenomas in 23 mice and 331 adenomas and 51 adenocarcinomas in 24 mice. The first tumor was observed during wk 43, and the av age at death was 68 wk. Fifty (100%) of the treated males developed 400 lung tumors: 114 adenomas in 26 mice and 237 adenomas and 49 adenocarcinomas in 24 mice. The first tumor was seen during wk 37, and the av age at death was 64 wk. The incidence of lung tumors in the untreated controls was 15% in females and 22% in males; the difference in tumor incidence between the treated and untreated mice was highly significant ($p < 0.0001$). The treatment had no detectable tumorigenic effect in other organs. (20 refs)

78-3119 **Early Proliferative Defects Induced by Six Weekly Injections of 1,2-Dimethylhydrazine in Epithelial Cells of Mouse Distal Colon.** (Eng) Deschner, E. E. (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY, 10021). *Z Krebsforsch* 91(2): 205-216; 1978.

Early histological and kinetic response of the colonic mucosa of CF$_1$ mice to 1,2-dimethylhydrazine (DMH) have been followed daily after just one injection and then weekly after 5 additional treatments. DMH was injected subcutaneously at a dose of 20 mg/kg body wt. To compensate for dramatic cell loss at 48 hr, marked elevation of the ^{3}H(TdR) labeling index with widening of the proliferation zone to the luminal surface of crypts occurred 2-4 days after initial treatment. At the fourth post-injection day, the regenerating mucosa showed decreased mucin production and structural alterations in crypts such as bifurcations and budding. Recovery of normal crypt histology, crypt cell number, mitotic frequency and labeling index was completed by 7 days. Focal atypia restricted to single isolated crypts were present afte 3 injections of the carcinogen. Replacement of lethall damaged cells 2-4 days after initial injection involve DNA synthesis in an increased number of epithelia cells in the mid portion of colonic crypts with som activity of cells in the upper crypt. This expansio of the proliferative compartment in the mid and upper portions of the crypts which has previously been noted in large bowel mucosa and some patients with a history of colorectal cancer was again evident a wk following the fourth, fifth and sixth DMH injections, indicating the existence of more permanent defect in the regulatory control of cell proliferation at a time when areas of focal atypia were increasing in number. 78-3123 **Studies on N-Nitroso Derivatives of N-Methylcarbamate Insecticides (III). Mutagenicity of N-Nitroso Derivatives of 3-Methylphenyl N-Methylcarbanate, 3,4-Dimethylphenyl N-Methylcarbamate and Naphhyl N-Methylcarbamate for *Salmonella typhimurium*.** Eng) Sakai, A. (Natl. Inst. Hygienic Sciences, 18-1, amiyoga 1-chome, Setagaya-ku, Tokyo, Japan); Yoshiawa, K.; Kurata, H.; Tanimura, A. *J Food Hyg Soc Jpn* 9(1): 122-125; 1978.

3-Methylphenyl N-methylcarbamate, 3,4-dimethylphenyl N-methylcarbamate, and naphthyl N-methylcarbamate and heir N-nitroso derivatives were tested for mutagenicity in *Salmonella typhimurium* strains TA100 and TA98. In the absence of a metabolic activation system (a rat liver microsome preparation, S-9 mix), the nitroso derivatives were mutagenic for strain TA100 but not for strain TA98, indicating that the mutations were due to base-pair substitutions. The S-9 mix inactivated the mutagenicity of the nitroso derivatives for TA100. With or without the S-9 mix, the N-methylcarbamate insecticides were nonmutagenic for TA100 and TA98. (17 refs)

78-3124 **Changes in Liver Nuclear Protein Metabolism after a Single Dose of Urethane to Suckling Mice.** (Eng) Gronow, M. (Cancer Res. Unit, Dept. Biology, Univ. York, Heslington, York Y01 5DD, England); Lewis, F. A. *Chem Biol Interact* 19(3): 327-338; 1977.

The rate of synthesis and the composition of liver nuclear proteins were examined for up to 24 hr after the sc injection of a single carcinogenic dose (1.2 mg/g body wt) of urethane into 8- to 9-day-old C57BL/A mice. There was an immediate decrease in liver DNA synthesis that reached a max 16-18 hr after injection and returned to normal after 48 hr. When the nuclear proteins were radiolabeled, the nonhistone protein (NHP) fraction showed a significant decrease in specific activity 8-18 hr after injection of urethane and a slight increase in specific activity after 24 hr. Histone and residual proteins did not show any significant change. Analysis of liver NHP by electrophoresis showed no distinctive differences following urethane injection. Isoelectric focusing, however, indicated that urethane induced some changes in protein content and synthesis, the most noticeable of which were an increase in a protein component having an isoelectric point (pI) of 7.35 and the appearance of new bands at pI's of 7.85 and 5.55 in the 18-hr-treated livers. The ^{3}H tryptophan labeling pattern indicated that the changes were not due to an increased synthesis of these components. Twenty-four hours after urethane injection, there appeared to be an increased rate of NHP synthesis, particularly the protein component with a pI of 5.65. No differences were detected by electrophoresis in the histone and residual protein fractions of treated and control livers. (27 refs)

78-3125 **Studies on N-Butyl-N-nitrosourethan-induced Cancers of the Esophagus and the Forestomach of Rats.** (Eng) Yasumoto, T. (Second Surgical Div., Yamaguchi Univ. Sch. Medicine, Ube, Umaguchi 755, Japan). *Arch Jpn Chir* 47(2): 156-168; 1978.

Donryu rats were treated with N-butyl-N-nitrosourethan (BNUR: 0.04% in the drinking water for 20-40 wk) and then with copper-containing bleomycin (BLM: 250 mg/kg as a single im injection, or 2 mg/kg im 2x/wk for 8 wk), and the distribution of BLM was studied in the esophagus and in the resulting squamous cell carcinomas. BNUR alone induced multiple papillomas in the esophagus and forestomach in all treated rats and squamous cell carcinomas in 26/29 rats. Twenty-four of the cancers were well-differentiated squamous cell carcinomas, and 2 were poorly differentiated. One of the most prominent features of these cancers, none of which metastasized, was the occurrence of multiple tumors extending from the esophagus to the forestomach. In rats given a single dose of BLM, the compound was found in greater concentrations in the cancer lesions than in the normal esophagus or papillomas; the distribution in the well- and poorly differentiated carcinomas did not differ. Under the polarizing microscope, the tonofibrils in the cells glittered. The tonofibrils in the well-differentiated carcinomas, but not in the poorly differentiated tumors, had the same appearance as those in normal squamous epithelium. Multiple BLM injections were fairly effective on the BNUR-induced carcinomas, although vacuolation and pyknosis of the nucleus and eosinophilic changes in the cancer cells were observed. The BLM-treated cancer pearls glittered more than the untreated cancer pearls under the polarizing microscope. (27 refs)

78-3126 **Effect of Implantation of Embryonal Liver Cells on Antibody Formation and Urethane-induced Carcinogenesis.** (Rus) Kraskovskii, G. V. (Inst. Genetics and Cytology, Minsk, USSR); Kagan, L. F. *Dokl Akad Nauk BSSR* 22(2): 181-184; 1978.

The effect of embryonal liver cell implantation on urethane-induced pulmonary carcinogenesis and antibody formation was studied in Af mice (urethane-sensitive) and (Af x C3H/Sn)F1 mice (C3H/Sn line is urethane-resistant). The mice were inoculated ip with urethane (1 mg/g) and, 1 day later, with 50 x 10^6 Af or C3H/Sn embryo liver cells. On the next day, animals were immunized with sheep RBC (100 x 10^6). Although the liver cell injection normalized urethane-inhibited antibody formation (hemagglutinin titer was 7.0 vs 5.6 in animals treated with urethane alone), it did not prevent urethane-induced pulmonary carcinogenesis. The av number of adenomas per mouse was 9.5, compared with 9.3 in mice inoculated with urethane alone. (10 refs)

78-3127 **Increased Activity of Rat Liver Messenger RNA and of Albumin Messenger RNA Modulated by Thioacetamide.** (Eng) Chakrabartty, P. K. (Lab. Pathophysiology, NCI, NIH, Bethesda, MD, 20014); Schneider, W. C. *Cancer Res* 38(7): 2043-2047; 1978.

The daily ip administration of 0.2 ml thioacetamide, a hepatocarcinogen, to male Sprague-Dawley rats increased the activity of liver messenger RNA, as determined by the wheat germ protein synthesis assay. The synthesis of total protein was increased by about 2.5-fold after 4 days of treatment. The treatment also increased the relative quantity of polyadenylic acid-containing RNA. Immunoprecipitation studies showed that albumin synthesis directed by messenger RNA was increased disproportionately, reaching a level five to six times the control level after 4 days of thioacetamide administration. (24 refs)

78-3128 **Carcinogens Inhibit DNA Synthesis with Isolated DNA Polymerases from *Escherichia coli.*** (Eng) Berthold, V. (Max-Planck-Institut fur medizinische Forschung, Abteilung Molekulare Biologie, Jahnstrasse 29, 6900 Heidelberg, W. Germany); Thielmann, H. W.; Geider, K. *FEBS Lett* 86(1): 81-84; 1978.

The effects of N-acetoxy-2-acetylaminofluorene (N-AAF) and N-methyl-N-nitrosourea (MNU) on DNA synthesis were determined using DNA polymerases isolated from *Escherichia coli.* DNA polymerase III holoenzyme was inhibited by 85% when RNA-primed single-stranded fd DNA was preincubated with N-AAF for 1 hr. Only 12% inhibition was observed when carcinogen, DNA polymerase III, and deoxynucleoside triphosphates were added simultaneously. Preincubation of the single-stranded DNA with increasing concentrations of N-AFF resulted in increasing inhibition of DNA synthesis. DNA polymerase III was inhibited 50% with 5 μM N-AAF; DNA polymerase I was inhibited less at the same concentration. Complex formation of fd DNA with the DNA-binding protein I prior to addition of 15 μM N-AAF reduced DNA synthesis by only 7%, compared with 75% with free DNA. Preincubation of the RNA-primed DNA template in 10 mM NMU for 10 min led to 70% inhibition; 26% inhibition was noted when polymerization was allowed to proceed after MNU addition. DNA polymerase III holoenzyme was slightly more sensitive to MNU than DNA polymerase I. (20 refs)

78-3129 **The Sebaceous-Gland Test.** (Eng) Longstaff, (Imperial Chemical Industries Ltd., Centr Toxicology Lab., Alderley Park, Cheshire, England). *Br Cancer* 37(6): 944-948; 1978.

The sebaceous gland test was evaluated as a short-term te for predicting carcinogenic potential. One hundred an twenty test compounds were dissolved singly in dimethyl su foxide and applied bid for 3 days to the shaved dorsolumb skin of male specific-pathogen-free Swiss-derived Alderl Park mice. A statistically significant reduction in the rat of sebaceous glands to hair follicles was taken to indica carcinogenic potential. A comparison of the percentage glands to follicles of control and treated skins demonstrat that the sebaceous glands of mice were sensitive to the actic of some chemicals. The test was 65% accurate in predictin carcinogenicity. When compounds giving false results we retested using a range of doses, only cyclophosphamid 4-aminobiphenyl, and 2-acetylaminofluorene could be adde to the list of identifiable carcinogens. Mouse skin sebaceo glands seemed insensitive to the action of benzidin o-dianisidine, dimethylnitrosamine, hexamethylphosphor mide, and urethane. The predictive value of the test was pa ticularly good for polycyclic aromatic hydrocarbons. Howe er, of 29 compounds causing >50% suppression of th glands, six were false-positives. It is concluded that this tec nique is not valid for comparing chemicals of different class for potency. (8 refs)

78-3130 **Loss of Adenylate Cyclase Hormonal Sensitivi ty in Chemically Transformed Epithelial Cell** (Eng) Makarski, J. S. (Dept. Surgery, Boston Univ. Sc Medicine, Boston, MA, 02118); Niles, R. M. *Exp Cell Re* 114(1): 191-195; 1978.

The hormonal sensitivity of adenylate cyclase from a norma rat liver epithelial cell line (K16) and it N-acetoxy-N-acetylaminofluorene-transformed derivativ (WB) was compared. Intact normal rat liver cells ha markedly increased cAMP levels after brief exposure to epi nephrine, isoproterenol, norepinephrine, or prost glandin E_1. The cAMP level rose very rapidly a reached a peak around 15 min, declining slightly 30 min. In contrast, the cAMP levels of chemical transformed cells were relatively unaffected by the same compounds, even after incubation for 3 hr. T basal adenylate cyclase activity of broken K-16 ce was six times higher than that of broken W-8 cells. T response to NaF was similar in the two cell lines, suggestin that the catalytic portion of the W-8 enzyme is not signi cantly altered. The response to catecholamines and prost glandins paralleled the intact cell studies. These data sugge that the W-8 cells have fewer or altered hormone bindin sites. It is also suggested that alteration in the function adenylate cyclase may be one way by which cells escape exte nal growth regulation. (11 refs)

8-3131 **Studies on the Transformation of Rat Embryo Cells of Low Passage by Carcinogenic Fluore- ylhydroxamic Acids and Their Acetate Esters.** (Eng) Kur- epa, H. (Lab. Cancer Res., Veterans Admin. Hosp., Min- eapolis, MN, 55417); Gutmann, H. R.; Malejka-Giganti, D.; rauss, A.; Cervenka, J.; Vosika, G. J.; Rydell, R. E. *In Vitro* 4(3): 261-270; 1978.

istar-Furth rat embryo cells of low passage were treated ith a single dose of certain carcinogenic fluorenylhydroxam- c acids and their respective acetate esters and examined for igns of in vitro transformation. Dishes of 10^4 cells ere exposed to 50 or 24 nanomoles (nmol) N-hydroxy- -fluorenylacetamide (N-hydroxy-2-FAA), 25 or 12 mol N-hydroxy-2-fluorenylbenzamide (N-hydroxy-2- BA), 50 or 25 nmol N-hydroxy-3-FAA, 50 or 25 mol N-acetoxy-2-FAA, 25 or 12 nmol N-acetoxy- -FBA, or 50 or 25 nmol N-acetoxy-3-FAA. All treated ell lines showed at least some signs of transformation, such s changes in phenotype, growth in soft agar, and agglutina- ion with concanavalin A. Furthermore, some changes in aryotype and loss of diploidy were observed. Electron mi- roscopy of the cells following chemical treatment revealed o viruslike particles; reverse transcriptase assay confirmed hese findings. Cells from these lines were then injected either c into newborn Wistar-Furth rats or im into weanling rats f the same strain. None of the inoculations resulted in tumor ormation. These findings suggest that malignant transforma- ion is a multistep process and that certain criteria of transfor- ation of rat embryo cells are associated with the initial tage(s) in which the cells are transformed without eing tumorigenic. (34 refs)

78-3132 **In Vitro Metabolism and Mutagenic Activation of 2-Acetylaminofluorene by Subcellular Liver Fractions from Cotton Rats.** (Eng) Schut, H. A. (Div. Cancer Treatment, NCI, NIH, Bethesda, MD, 20014); Thorgeirsson, S. S. *Cancer Res* 38(8): 2501-2507; 1978.

Biochemical parameters associated with in vivo 2-acetylaminofluorene (AAF) carcinogenesis and in vitro AAF mutagenesis in Salmonella were evaluated in subcellular liver fractions of the Cotton rat, a species resistant to AAF carcinogenesis. Low concentrations (1 μg/plate) of AAF or N-hydroxy-AAF (N-OH-AAF) were highly mutagenic (> 1,000 colonies/plate) in the presence of low concentrations (0.4 mg/plate) of microsomal protein. Deacetylation and mutagenicity of AAF and N-OH-AAF were partially inhibited by 0.001-0.1 μM paraoxon and completely inhibited by 100 μM, indicating involvement of a microsomal deacetylase in the mutagenic activation of AAF and N-OH-AAF. The activity of N-OH-AAF sulfotransferase in Cotton rat livers was one-third that of the Sprague-Dawley rat and it decreased cytosol-mediated N-OH-AAF mutagenesis 45%, indicating that this enzyme is not important in the mutagenic activation of N-OH-AAF. AAF mutagenesis with microsomes from untreated animals was much more sensitive to inhibition by 1-10 μM α-naphthoflavone (ANF) than that with microsomes from 3-methylcholanthrene (MC)-treated animals, and at 50 μM ANF this process was inhibited completely in both cases. AAF N-hydroxylase from untreated animals also exhibited a greater sensitivity to ANF (1-10 μM) than that of MC-treated animals, but the difference was much less pronounced; at 500 μM ANF, this difference was reversed, with the enzyme from MC-treated animals showing greater inhibition (90% vs 60%). Inhibition of aryl hydrocarbon hydroxylase required ANF concentrations > 10 μM, and the enzyme from MC-treated animals was more sensitive to this agent (60% inhibition) than that of untreated animals (35%). The Cotton rat appears to possess all the known enzyme systems to activate AAF into an ultimate carcinogen or mutagen. Exploration of other biochemical properties, such as interaction of AAF with subcellular macromolecules or in vivo AAF metabolism, may provide further insight into the resistance of this species to AAF carcinogenesis. (48 refs)

78-3133 **Gangliosides of Liver Tumors Induced by N-2-Fluorenylacetamide. II. Alterations in Biosynthetic Enzymes.** (Eng) Merritt, W. D. (Section Cytology, Yale Univ. Sch. Medicine, New Haven, CT, 06510); Morre, D. J.; Keenan, T. W. *J Natl Cancer Inst* 60(6): 1329-1337; 1978.

Activities of the enzymes of the monosialoganglioside pathway were studied in male Wistar rats fed a low-protein basal diet with or without 0.05% N-2-fluorenylacetamide. Livers, hyperplastic nodules, and hepatomas were analyzed throughout a 23-wk period of tumorigenesis. An early twofold elevation of monosialoganglioside G-M3 levels in precancerous tissues and nodules correlated with an early twofold increase in the specific activity of cytosine monophosphate-N-acetylneuraminic acid:lactosylceramide sialyltransferase of G-M3 biosynthesis. This increase was followed by increases in specific activities of the galactosyltransferases and sialyltransferases of G-M1 and G-D1a biosynthesis in well-differentiated hepatomas and in well-circumscribed, poorly differentiated hepatomas. The result was a thirtyfold increase in the products of the monosialoganglioside pathway (G-M1 + G-D1a) relative to the sum of the products of the disialoganglioside pathway (G-D3 + G-X). The property of invasiveness may be associated with this increasing ratio. (23 refs)

78-3134 **Toxicity and Frequency of Sister Chromatid Exchanges Produced by N-hydroxy-2-acetylaminofluorene (N-OH-AAF) in Human Lymphocytes (Meeting Abstract).** (Eng) Altenburg, L. C. (Univ. Texas Health Science Center, Medical Genetic Center, Houston, TX, 77030); Ray, J. H.; Jacobs, M. M. *Mutat Res* 53(1): 74-75; 1978. (no refs)

78-3135 **Unscheduled DNA Synthesis in Spermatogenic Cells of Mice Treated In Vivo with the Indirect Alkylating Agents Cyclophosphamide and Mitomen.** (Eng) Sotomayor, R. E. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Sega, G. A.; Cumming, R. B. *Mutat Res* 50(2): 229-240; 1978.

The effects of cyclophosphamide (CP) and mitomen (2,2′-dichloro-N-methyldiethylamine N-oxide: DMO) on DNA repair were studied in meiotic and postmeiotic germ cells of male (C3Hf x 101)F_1 mice using an in vivo unscheduled DNA synthesis (UDS) assay. Ethylmethanesulfonate (EMS), a compound that does not require metabolic activation, was also studied for comparison. Both CP and DMO (200 and 40 mg/kg ip, respectively) induced UDS in the meiotic through early-to-midspermatid stages, but no UDS was detected in late spermatids and mature sperm. EMS (200 mg/kg ip) produced a max UDS response in the germ cells immediately after treatment; CP and DMO did not produce a max response until approx 0.5-1.0 hr after injection. This delay is attributed to the time required for CP and DMO to be enzymatically activated to alkylating metabolites. Unlike the results found with EMS, mutation frequencies (dominant lethals, translocations, and specific-locus mutations) following CP treatment were not noticeably reduced in the germ cell stages in which UDS occurred. With DMO, mutations were induced only in mature spermatozoa, and these germ cell stages represented only a fraction of those in which no UDS was detected. These findings do not resolve the ambiguity of the relationship between DNA repair and the differential spermatogenic response of mice to genetic damage. (31 refs)

78-3136 **Does Cyclophosphamide Induce Bladder Cancer?** (Eng) Pearson, R. M. (Dept. Urology, Univ. Tennessee Center for the Health Sciences, Memphis, TN, 38163); Soloway, M. S. *Urology* 11(5): 437-447; 1978.

The case report of a 40-yr-old man with malignant lymphoma who subsequently developed adenocarcinoma of the urinary bladder is presented. Treatment of the lymphoma included the administration of 3 g of cyclophosphamide; this is the first reported case of an adenocarcinoma following cyclophosphamide therapy. The 13 previously reported cases of bladder tumors following cyclophosphamide therapy are reviewed. (91 refs)

78-3137 **Chromosome Aberrations Induced by Monomeric Acrylamide in Bone Marrow and Germ Cells of Mice.** (Eng) Shiraishi, Y. (Dept. Anatomy, Kochi Medical Univ., Nangoku City, Kochi 781-51, Japan). *Mutat Res* 57(3): 313-324; 1978.

The chromosomes of the marrow, spermatogonia, and primary spermatocytes of male DDY mice were examined quantitatively after the mice were treated with acrylamide (AA) po (500 ppm of diet for 1, 2, or 3 wk) or ip (single dose of 100, 150, or 200 mg/kg). Samples were taken at various times after treatment. A comparatively high frequency of chromatid exchanges and breaks was induced in the spermatogonia of the 3-wk po mice only (19% vs 2.4% in controls). However, the frequency of chromosome aberrations was not increased appreciably in the marrow cells of any of the mice. The number of mitotic cells was reduced significantly in the spermatogonia of all treated mice, especially 12 and 24 hr after the ip injections. Thus, it was not possible to examine the acute cytogenetic effects of AA on spermatogonia. The frequency of aneuploid and polyploid cells increased with time after treatment in both the marrow and spermatogonia cells. AA induced a significant number of chain quadrivalents, ring quadrivalents, fragments, and univalents in the primary spermatocytes, especially in ip mice. There was no noticeable increase in the sister chromatid exchange frequency over control levels in the marrow and spermatogonia cells. AA also reduced the testis wt significantly, which suggests that there is a correlation between AA-induced chromosome aberrations and cell killing. The findings of a high frequency of rearrangements and univalents in the primary spermatocytes is significant, but it is not known whether these aberrations are transmitted to the next generation. (21 refs)

78-3138 **Positive Interferant in the Chemiluminescent Detection of Nitrosamines.** (Eng) Gough, T. A. (Lab. Government Chemist, Stamford St., London SE1 9NQ, England); Webb, K. S. *J Chromatogr* 154(2): 234-237; 1978.

Although chemiluminescence is highly selective in detecting N-nitroso compounds, it is possible to observe a response from other (interfering) compounds at the retention times of volatile nitrosamines. Therefore, the chemiluminescence findings should be confirmed by mass spectrometry. (13 refs)

78-3139 **Structure-Activity Studies on Mutagenicity of Nitrosamines Using Molecular Connectivity.** (Eng) Kier, L. B. (Dept. Pharmaceutical Chemistry, Medical Coll. Virginia, Virginia Commonwealth Univ., Richmond, VA, 23298); Simons, R. J.; Hall, L. H. *J Pharm Sci* 67(5): 725-726; 1978.

The relationship between molecular structure and mutagenicity in the Ames test was investigated using 15 nitrosamines, including alkyl, guanidino, and ureido derivatives. The structure-activity relationships were examined by the molecular connectivity method, which allows the evaluation of structural features influencing physical property values and biological activity. There was a good relationship etween a molecular connectivity description of structure and nutagenic potency. This finding could be used to develop a heoretical prediction of mutagenic potential in discrete hemical classes of molecules. (11 refs)

8-3140 **The Carcinogenic Effect of β Oxidized Dipropylnitrosamine in Mice. II. 2-Hydroxypropyl-N-propylnitrosamine and 2-Oxo-propyl-N-propylnitrosamine.** (Eng) Dickhaus, S. (Abteilung fur Experimentelle Pathologie, Medizinische Hochschule, Hannover, Karl-Wiechert-Allee 9, D-3000, Hannover 61, Germany); Reznik, G.; Green, U.; Ketkar, M. *Z Krebsforsch* 91(2): 189-193; 1978.

The carcinogenic effects of 2-hydroxypropyl-N-propylnitrosamine (2-HPPN) and 2-oxo-propyl-N-propylnitrosamines (2-OPPN) were studied in female NMRI mice. The chemicals were given sc at 0.2, 0.1, and 0.05 of the LD$_{50}$ once weekly for life beginning at 6 wk of age. With 2-HPNN, survival time decreased with increasing dosage, and tumor incidence increased (from 84% to 100%) with increasing survival period. Adenomas, papillomas, adenocarcinomas, and epidermoid carcinomas occurred in the nasal cavities; alveogenic adenomas and adenocarcinomas arose in the lungs; and hemangioendotheliosarcomas, cholangiomas, and one mixed tumor arose in the liver. Survival and tumor multiplicity increased with increasing dose of 2-OPPN. Tumor incidence was 86%-92%. Papillomas and adenocarcinomas arose in the nasal and paranasal cavities; intrabronchial papillomas, alveogenic adenomas, and adenocarcinomas arose in the lungs; and all liver tumors were hemangioendotheliosarcomas, except for two cholangiomas and one mixed tumor. Neither 2-HPPN nor 2-OPPN induced tumors in the nasopharyngeal duct or larynx. The carcinogenicity of the β-metabolites of dipropylnitrosamine cannot be unequivocally associated with the carcinogenic effect of the parent compound. (12 refs)

78-3141 **Detection of N-Nitrosodimethylamine by Gas Chromatography-Methane Chemical Ionization Mass Spectrometry with Single Ion Monitoring.** (Eng) Mach, M. H. (Chemistry and Physics Lab., Ivan A. Getting Labs., Aerospace Corp., El Segundo, CA, 90245); Pallos, A. *Anal Lett* 11(1): 97-102; 1978.

Gas chromatography-methane chemical ionization mass spectrometry with single-ion monitoring was used to detect N-nitrosodimethylamine (NDMA) at concentrations <50 ppb. In water, concentrations as low as 25 ppb could be detected; similar findings were obtained with NDMA in hexane. This method is intended for relatively pure samples known to contain the compound and not for the analysis of NDMA in unknowns. (18 refs)

78-3142 **Lipoperoxidative Effects on Liver Rough Microsomal Membranes and the Ribosome-Membrane Complex.** (Eng) Shires, T. K. (Dept. of Pharmacology, The Toxicology Center, Coll. of Med., Univ. of Iowa, Iowa City, IA, 52242). *Lab Invest* 38(6): 693-702; 1978.

A direct and quantitative assay of the loss of radioactively labeled ribosomes from the membranes of rough microsomal preparations from rat liver was undertaken after the membranes were incubated with carbon tetrachloride (CCl$_4$), dimethylnitrosamine (DMNA), or aflatoxin B$_1$. Incubations were carried out in the presence of NADPH and/or varying concentrations of K^+. None of these compounds fostered the detachment of ribosomes from the membrane in vitro under conditions that supported their metabolism. Lipoperoxidation caused by CCl$_4$ or NADPH did, however, stimulate detachment in the presence of elevated K^+ concentrations (750 mM). Rough membranes isolated from the liver of rats given lethal doses of CCl$_4$, but not DMNA, also responded to high K^+ concentrations with increased ribosome detachment. Three changes in the polysome-membrane complex were elicited by lipoperoxidation: an apparent loosening of the linkage involving peptidyl transfer RNA and the membrane; an inactivation of the ion-sensitive binding sites for the ribosome, as shown by the decreased acceptance of exogenous ribosomes by stripped lipoperoxidized rough membranes; and a site stabilization by stripped ribosome occupation of the binding site at the time of lipoperoxidation. The disappearance of rough endoplasmic reticulum in the livers of animals ingesting compounds such as CCl$_4$ seems to arise from the failure of polysome assembly on membranes of the endoplasmic reticulum rather than from the detachment of active ribosomes from the membranes. (26 refs)

78-3143 **Hydroxyurea-sensitive Thymidine Incorporation in Rat Liver and Kidney Following Administration of Dimethylnitrosamine.** (Eng) Stewart, B. W. (Sch. Pathology, Univ. New South Wales, P.O. Box 1, Kensington, New South Wales, Australia 2033); Brian, M. J. *Cancer Lett* 4(3): 155-161; 1978.

The sensitivity of ^{3}H-thymidine incorporation to inhibition by hydroxyurea (HU) was determined in the livers and kidneys of female Wistar rats treated with dimethylnitrosamine (DMN: 30 or 40 mg/kg ip). In control animals, HU (50-250 mg/kg ip) inhibited thymidine incorporation by 70%. Twelve hours after DMN administration, hepatic thymidine incorporation was unaffected by 50 mg/kg HU, but a progressive reduction in incorporation occurred as the dose of inhibitor was increased. In the kidney, HU-insensitive thymidine incorporation was observed only in rats conditioned by a diet that increased the renal metabolism of DMN. At 72 hr after DMN treatment, thymidine incorporation in both liver and kidney was inhibited $>70\%$ by 50 mg/kg HU. The results support the use of HU to study DNA repair in intact animals. (19 refs)

78-3144 **RNA Metabolism and Poly(A) Distribution in Mouse Liver Following Administration of**

Dimethylnitrosamine. (Eng) Hultin, T. (Wenner-Gren Inst., Univ. Stockholm, S-113 45 Stockholm, Sweden); Eriksson, B.; Nygard, O.; Von Der Decken, A. *Chem Biol Interact* 21(1): 45-58; 1978.

Dimethylnitrosamine (DMNA: 1% soln, 25-75 mg/kg) was administered by stomach tube to NMRI mice, and the effects of the compound on RNA metabolism and on poly(A) distribution in the liver were determined. DMNA inhibited RNA synthesis in the liver markedly, but the intracellular nucleotide pattern, rate of nucleotide synthesis, and phosphorylation ratio were unaffected. In addition, an unidentified, probably nonnucleotide, component in the acid-soluble liver fraction was reduced selectively, and the RNA polymerase activity of isolated liver nuclei was decreased within 45 min. Both Mg^{2+}- and $Mn^{2+}/(NH_4)_2SO_4$-stimulated polymerase activity was decreased. The inhibition of RNA synthesis involved the entire complement of RNA, including poly(A)-containing nuclear and cytoplasmic RNA and isolated RNase-resistant poly(A) sequences. The transfer of labeled RNA from the nucleus to the cytoplasm was not impaired. There was no detachment of poly(A)-containing RNA from the microsomes, and the proportion of tightly membrane-bound microsomal RNA and poly(A) sequences was not reduced, as determined by a flotation technique. Sedimentation analysis showed that there was no breakage or shortening of the poly(A) chains. Even at the high DMNA levels, there was no decrease in the proportion of poly(A)-containing RNA and poly(A) sequences tightly bound to endoplasmic membranes and no evidence of poly(A) degradation. (31 refs)

78-3145 **Qualitative Alterations in Plasma Esterases in BALB/c Mice Following the Administration of Diethylnitrosamine.** (Eng) Davidson, K. A. (Biology Div., Oak Ridge Natl. Lab., P.O. Box Y, Oak Ridge, TN, 37830); Tyndall, R. L.; Clapp, N. K. *Chem Biol Interact* 21(1): 19-27; 1978.

Female BALB/c mice were treated with dimethylnitrosamine (DEN: in the drinking water for 7 wk), and their plasma esterases and those of untreated mice were analyzed qualitatively. Selected nonspecific plasma esterases, separated by polyacrylamide gel electrophoresis, were altered following DEN treatment. These alterations included a decreased preference for naphthyl butyrate as a substrate relative to naphthyl acetate; a decreased sensitivity to enhancement by divalent cations such as Ca^{2+}, Mg^{2+}, and Mn^{2+}; and an increased sensitivity to inhibition by eserine. All the affected esterase species were also altered quantitatively, and some were testosterone-dependent. The differential response of the plasma esterases of the treated mice to Mn^{2+}, eserine, and substrate are interesting in view of the fact that their electrophoretic mobilities were not altered. (23 refs)

78-3146 **Singlet Oxygen Formation During Peroxidase Catalyzed Degradation of Carcinogenic N-Nitrosamine.** (Eng) Duran, N. (Dept. Biochemistry, Universidade de Sao Paulo, Instituto de Quimica, C.P. 20780, Sao Paulo, Brazil); Faljoni, A. *Biochem Biophys Res Commun* 83(1): 287-294; 1978.

Evidence is presented for the formation of singlet oxygen and chemiluminescence during the decomposition of nitrosamines catalyzed by peroxidase. The reaction medium contained 40 mM diisopropyl-N-nitrosamine and 3 μM horseradish peroxidase in 0.1 phosphate buffer, pH 7.4. The singlet oxygen traps 2,5-diphenylfurane and 1,3-diphenylisobenzofurane were oxidized to *cis*-benzoylethylene and *o*-dibenzoylbenzene during the decomposition. Singlet oxygen quenchers such as butylated hydroxytoluene and 3,5-ditertbutyl-4-hydroxybenzylalcohol inhibited this conversion and also the chemiluminescence accompanying the catalyzed reaction. Chemiluminescence was enhanced by 1,4-diazobicyclo(2.2.2)octane, fluorescein, eosin, rhodamine B, and rose bengal, but little effect was detected with 9,10-dibromoanthracene-2-sulfonate, 9,10-diphenylanthracene-2-sulfonate, and anthracene-2-sulfonate. In the absence of an enhancer, an emission spectrum in the region 560-600 nanometers was observed. It is suggested that singlet oxygen formation could play an important role in nitrosamine carcinogenesis. (27 refs)

78-3147 **Changes of the APUD Cell System During Nitrosamine-Induced Pulmonary Carcinogenesis in a Syrian Golden Hamster (Meeting Abstract).** (Ger) Reznik-Schuller, H. (Hannover, W. Germany). *Zentralbl Allg Pathol* 122(1/2): 139-140; 1978. (no refs)

78-3148 **Effect of L-Tryptophan on Diethylnitrosamine and 3′-Methyl-4-N-dimethylaminoazobenzene Hepatocarcinogenesis.** (Eng) Evarts, R. P. (Carcinogen Metabolism and Toxicology Branch, NCI, Bethesda, MD 20014); Brown, C. A. *Food Cosmet Toxicol* 15(5): 431-435; 1977.

The effect of L-tryptophan (TP) on hepatocarcinogenesis in male Wistar rats fed either 3′-methyl-4-N-dimethylaminoazobenzene (3′-MeDAB) or diethylnitrosamine (DENA) was investigated. There were six groups of rats. Group I (20 rats) received no treatment; Group 2 (20 rats) received a diet containing 1% TP; Group 3 (25 rats) received a 0.002% solution of DENA in the drinking water; Group 4 (29 rats) received DENA + TP; tryptophan; Group 5 (29 rats) received 0.05% 3′-MeDAB in the diet; and Group 6 (30 rats) received 3′-MeDAB + TP. DENA was administered for 128 days, 3′-MeDAB for 96 days. Thereafter, basal or 1% TP was given until day 166. No tumors were found in the first two groups. Group 3 contained 22 animals with tumors; 13 anaplastic (A) and 4 well-differentiated

(W-D) hepatocellular tumors and 5 hemangioendothelial sarcomas, plus 5 metastases. Group 4 had 17 animals with tumors: 16 hepatocellular tumors (8A, 8W-D) and 1 hemangioendothelioma sarcoma, plus 6 metastases. Group 5 had 24 animals with hepatocellular tumors, 21 A and 2 W-D, plus 10 metastases. Group 6 had 12 animals with tumors: 10 hepatocellular tumors (5A, 5 W-D) and 2 cholangiomas plus 4 metastases. These findings indicate that TP decreases the incidence of 3′-MeDAB- and DENA-induced liver tumors in rats, but it has no effect on the location and incidence of esophageal tumors in DENA-fed animals. (26 refs.)

78-3149 **Liver Cell-mediated Mutagenesis of Mammalian Cells by Liver Carcinogens.** (Eng) Langenbach, R. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NB, 68105); Freed, H. J.; Huberman, E. *Proc Natl Acad Sci USA* 75(6): 2864-2867; 1978.

A cell-mediated mutagenesis assay was developed in which primary cultures of rat liver cells were used to activate two classes of liver carcinogens, nitrosamines and aflatoxins, and Chinese hamster V79 cells were used to detect their mutagenic metabolites. Mutations in the V79 cells were characterized by resistance to ouabain (oua-r). When the liver and V79 cells were cocultivated in the presence of N-nitrosodimethylamine (DMN), N-nitrosodiethylamine, and aflatoxin B_1, oua-r mutants were induced in the V79 cells. When the liver cells were absent, the carcinogens did not induce oua-r mutants, which suggests that the reactive intermediate(s) of these carcinogens is stable enough to be transferred from the liver cells to the V79 cells. The analogs N-nitrosomethyl-tert-butylamine and aflatoxin G_2 were not mutagenic. Mutation frequency increased with increasing doses of the carcinogens and with increasing numbers of liver cells seeded. Liver cell-mediated mutagenesis may be more sensitive than liver microsome-mediated mutagenesis: with 2×10^6 attached liver cells from noninduced animals, a DMN concentration of only 1.4 mM was required to enhance mutation frequency 90-fold, whereas in other studies, 50 mM DMN was required to obtain a similar increase in the mutation frequency of V79 cells with microsomes from induced animals. The liver cell-mediated assay may be a sensitive assay for screening chemical carcinogens. (37 refs)

78-3150 **Heritable Translocation Test on Random-bred Mice after Prolonged Triethylenemelamine Treatment.** (Eng) Sheu, C. W. (Genetic Toxicology Branch, Div. Toxicology, Food and Drug Admin., Washington, DC, 20204); Moreland, F. M.; Oswald, E. J.; Green, S.; Flamm, W. G. *Mutat Res* 50(2): 241-250; 1978.

Heritable translocation and dominant lethal tests were performed with random-bred Swiss albino male mice that had received triethylenemelamine (TEM) at concentrations of 0.0125, 0.025, or 0.050 mg/kg/day in the drinking water for 4 wk. Following treatment, the mice were mated for 3 successive wk for analysis of dominant lethality and production of F_1 progeny. The dominant lethal effect was statistically significant for offspring of the first 2 wks of mating. Potential translocation carriers among F_1 males were selected after two breedings and confirmed by cytogenetic analysis. Translocation heterozygotes were obtained in offspring from the TEM-treated groups, but not in offspring from control groups. In F_1 males produced from the first week of mating, the frequencies of translocations were 0%, 1.7%, 6.2%, and 10% for the control and 0.0125-, 0.025-, and 0.050-mg/kg/day groups, respectively. The frequencies in F_1 males produced in the third week of mating were 0% and 2.1% for the control and 0.050-mg/kg/day group respectively. F_1 males from the second week of mating were not studied. TEM-induced dominant lethality and heritable translocations were most prominent in the first week of mating after 4 wk of treatment. Heritable translocations appeared to be a more sensitive end point than dominant lethal mutations for measuring the mutagenic effects of TEM. (10 refs)

78-3151 **Effect of Cholecystoduodenostomy and Choledochostomy in Pancreatic Carcinogenesis.** (Eng) Pour, P. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NB, 68105); Donnelly, T. *Cancer Res* 38(7): 2048-2051; 1978.

The pancreatic carcinogen N-nitrosobis(2-oxopropyl)amine (BOP) was administered to Syrian golden hamsters after cholecystoduodenostomy and choledochostomy to investigate a possible bile reflux mechanism as a factor in pancreatic carcinogenesis. Ten animals received weekly sc injections of BOP (5 mg/kg) for 20 wk, beginning 1 wk after surgery. Another three hamsters received 5 mg/kg BOP as a single injection at the 11th wk after surgery, and seven hamsters served as untreated controls. All 13 treated hamsters developed pancreatic neoplasms that were classified as adenomas, intraductal carcinomas, and adenocarcinomas. The lesions were similar in morphology, multiplicity, and distribution to those of animals in other studies in which the above surgery was not performed. Consequently, the effect of bile can be excluded as a mediating factor in pancreatic carcinogenesis. In this as well as in previous experiments, most of the induced pancreatic tumors were of ductular origin, and many seemed to develop within or around the islets. The preference for the peri- and intrainsular ductules as sites of cancer induction could be due to a greater exposure of the responsive ductular cells to the blood-borne carcinogen because of a marked vascularity of the islets. This would explain why limited or single BOP doses in previous studies and in this experiment primarily affected the peri- and intrainsular ductules. (9 refs)

78-3152 **Carcinogenicity of Acetoxymethyl-methyl-nitrosamine after Subcutaneous, Intravenous and**

Intrarectal Applications in Rats. (Eng) Habs, M. (Institut Toxikologie und Chemotherapie, Im Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Schmahl, D.; Wiessler, M. *Z Krebsforsch* 91(2): 217-221; 1978.

In comparison to the known carcinogenic properties of acetoxymethyl-methyl-nitrosamine (AMMN) after oral or intraperitoneal application the dimethylnitrosamine derivative was tested by subcutaneous, intravenous and intrarectal route in male Sprague-Dawley or Wistar rats. AMMN proved to be primarily a locally acting carcinogen. However, a second mode of action is indicated by systemic carcinogen properties found after iv and sc applications. The lung and heart, and to a less extent the kidney and ear duct were found as target organs of distant carcinogenic response. (no refs)

78-3153 **Urinary Bladder Neoplasms in Syrian Hamsters after Administration of N-Nitroso-N-methyl-N-dodecylamine.** (Eng) Althoff, J. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NB, 68105); Lijinsky, W. *Z Krebsforsch* 90(3): 227-231; 1977.

The carcinogenic effect of N-nitroso-N-methyl-N-dodecylamine (NMDA) was examined in Syrian hamsters. NMDA was given intragastrically once a week for life to three groups of hamsters at dose levels corresponding to 0.05, 0.025, and 0.0125 of the LD$_{50}$. Tumors were observed 36 wk after the start of the treatment, and the incidence showed a positive dose-response relationship. The urinary bladder was the main target organ, followed by the lungs. Lung tumors occurred only in female hamsters, whereas males more frequently had neoplasms of the nasal cavity and digestive tract. It appears questionable as to whether urinary metabolites of NMDA can be specifically linked to urinary bladder carcinogenesis. A urogenic mode of action would also not explain the simultaneous occurrence of neoplasms in organs other than the urinary bladder. (13 refs)

78-3154 **Carcinogenicity of Subcutaneously Injected N-Nitrosoheptamethyleneimine in European Hamsters.** (Eng) Reznik, G. (Abteilung fur Experimentelle Pathologie, Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, 3000 Hannover 61, W. Germany); Mohr, U.; Lijinsky, W. *J Natl Cancer Inst* 61(1): 239-243; 1978.

The carcinogenicity of sc injected (once weekly for life) N-nitrosoheptamethyleneimine (NHMI) was studied in male and female European hamsters (45 of each sex). The hamsters were divided into three groups that received 20%, 10%, or 5% of the LD$_{50}$ (330 mg/kg for males and 220 mg/kg for females). Av survival times decreased with increasing dose levels of NHMI. A high percentage (96%-100%) of lung tumors was observed in all dose groups. They were histologically diagnosed as adenomas, adenocarcinomas, squamous cell carcinomas, or mixed cell carcinomas, with the squamous cells lying centrally in the tumor. Nasal cavity tumors developed in 100% of all treated males and females; 78% of these tumors were malignant (squamous cell carcinomas), and they frequently infiltrated and destroyed the nasal and maxillary bone. As many as 53% of the treated animals developed small squamous cell papillomas in the forestomach. Five animals had squamous cell carcinomas of the forestomach. One tracheal papilloma and one laryngeal squamous cell carcinoma were seen in two males from the group given the highest dose of NHMI. These results together with those of earlier investigations suggest an influence of the mode of application of NHMI on the tumor response in European hamsters. (10 refs)

78-3155 **Mutagenicity of Nitrosourea Compounds for *Salmonella typhimurium*: Brief Communication.** (Eng) Auletta, A. E. (JRB Associates, Inc., 8400 Westpark Dr., McLean, VA, 22101); Martz, A. G.; Parmar, A. S. *J Natl Cancer Inst* 60(6): 1495-1497; 1978.

The nitrosourea derivatives 1,3-bis(2-chloroethyl)-1-nitrosourea (BCNU), 1-(2-chloroethyl)-3-cyclohexyl-1-nitrosourea (CCNU), 1-(2-chloroethyl)-3-(4-methylcyclohexyl)-1-nitrosourea (Me-CCNU), and 1-methyl-1-nitrosourea (MNU) were tested for mutagenicity in vivo and in vitro using *Salmonella typhimurium* strains G46 and TA1530. In vitro tests of these compounds at concentrations of 1-1,000 μg/plate indicated that all four were mutagenic; MNU, CCNU, and Me-CCNU were also mutagenic in the host-mediated assay in Swiss albino mice. 3-(1-Adamantyl) -1- (2-chloroethyl) -1- nitrosourea, 3-(1-adamantyl)-1-(2-fluoroethyl) -1- nitrosourea, 1,1′- (4,4′-biphenylylenedimethylene)-bis[3- (2-chloroethyl)] -3-nitrosourea, and 1,1′-(1,4-cyclohexylenedimethylene)bis[3-(2-chloroethyl)] -3-nitrosourea (NSC-120337) were also tested for in vitro mutagenicity at concentrations of 1-1,000 μg/plate using strain G46. All compounds were mutagenic except for NSC-120337. However, this may have been an indication of the instability of NSC-120337 in soln rather than a true reflection of its mutagenic potential. All eight compounds were then tested in a repair test with *S. typhimurium* strains TA1978 and TA1538. The results of this test were negative, reflecting the insensitivity of these strains to ethylating and methylating agents. The insensitivity of the host-mediated assay is also discussed. (16 refs)

78-3156 **Modulation of Carcinogen Chromatin-DNA Interaction by Polyamines.** (Eng) Rajalakshmi, S. (Dept. Pathology, Univ. Toronto, Medical Sciences Building, Toronto, Ontario M5S 1A8, Canada); Rao, P. M.; Sarma, D. S. *Biochem Biophys Res Commun* 81(3): 936-940; 1978.

The effect of polyamines on the methylation of chromatin DNA in vitro by N-methyl-N-nitrosourea (MNU) was investigated. Hepatic chromatin was isolated from male Fischer rats and exposed to 4 ml of a soln containing 2 micromoles (μmol)/ml MNU for 2 hr. The addition of 0.0125, 0.025, and 0.05 μmol spermine/ml incubation mixture containing 150-200 μg of chromatin DNA inhibited DNA methylation by 27%, 56%, and 86%, respectively. Similar results were obtained when rat liver DNA was substituted for liver chromatin. Spermidine had a similar effect, but putrescine was less effective (50% inhibition at 0.1 μmol/ml). At about 86% inhibition, methylation at the N^3 position of adenine was inhibited by 100% and that at the N^7 or O^6 position of guanine was inhibited by 80%. However, spermine did not inhibit the methylation of 2-deoxy-5′-guanilic acid included as an internal control. Further studies indicated that the inhibition of MNU-induced methylation of DNA by polyamines was not due to a suppression of the release of active methyl groups from MNU during its decomposition in the incubation mixture. The polyamines modulate carcinogen-DNA interaction by altering the net charge and/or the conformation of DNA. (15 refs)

78-3157 **The Effect of Chloramphenicol on the Toxic and Therapeutic Activity of N-Nitrosomethylurea.** (Rus) Bogush, T. A. (Lab. Chemical Carcinogenesis, Cancer Res. Center, Moscow, USSR); Konopleva, I. A.; Shabad, L. M. *Vopr Onkol* 23(12): 66-70; 1977.

The effect of the antibiotic chloramphenicol (CAP) on the toxicity and therapeutic activity of N-nitrosomethylurea (NMU) was studied in CBA mice. Two series of experiments were carried out. In the first series, mice were given CAP (1 mg/g, po, for 5 days); 2 hr after the last CAP administration, animals were inoculated sc with NMU (0.05-0.1 mg/g). All control mice (treated with NMU alone) died by day 14 after injection; NMU + CAP provided 65% survival. In the second series, mice were inoculated ip with 2.5 x 10^6 Ehrlich ascites carcinoma cells; on the next day, some of the animals started to receive CAP (1 mg/g/day, po). Five days later all animals were inoculated with NMU (0.05-0.075 mg/g, sc). The av duration of survival of mice treated with NMU alone and with NMU + CAP was increased by 2-3 days, compared with untreated controls. CAP administration decreased the number of tumor cells in the ascites fluid: on day 6 after carcinoma transplantation, mice treated with NMU + CAP had approx 1.5 x 10^6 tumor cells, compared with 3.5 x 10^6 cells in mice treated with NMU alone and approx 4 x 10^6 cells in untreated controls. 78-3159 **Genetic Basis of Susceptibility for Development of Neoplasms Following Treatment with N-Methyl-N-nitrosourea (MNU) or X-Rays in the Playfish/-Swordtail System.** (Eng) Schwab, M. (Genetisches Institut der Justus Liebig-Universitat Giessen, Heinrich-Buff-Ring 58-62, D-6300 Giessen, W. Germany); Haas, J.; Abdo, S.; Ahuja, M. R.; Kollinger, G.; Anders, A.; Anders, F. *Experientia* 34(6): 780-782; 1978.

The susceptibility of 65 defined genotypes, including nonhybrids, F$_1$ hybrids, and backcross hybrids, of xiphophorine fish to tumor induction by x-rays or N-methyl-N-nitrosourea (MNU) was analyzed to determine the role of genetic factors. Both 6-wk- and 6-mo-old fish were exposed in tanks to an aqueous soln (10^{-3} M) of MNU for 1 hr at 2-wk intervals for a total of four treatments. Additional fish underwent whole-body irradiation (1,000 R for 45 min, 3 treatments at 6-wk intervals). Tumor development was age-dependent, with the younger group being much more susceptible. Benign and malignant melanoma, neuroblastoma, and fibrosarcoma were the most prevalent tumor types. Other tumor types included squamous cell carcinoma, epithelioma, adenocarcinoma of the kidney and thyroid, hepatoma, rhabdomyosarcoma, and lymphosarcoma. The neoplasms developed almost exclusively in the backcross hybrids. Certain genotypes carrying specific chromosomes, which could be identified by phenotypic markers, were susceptible to tumor development, but others lacking these chromosomes were not susceptible. This suggests that the susceptibility has a genetic basis. The most likely mechanism is a somatic mutation. (35 refs)

78-3160 **Inhibition of Post-replication Repair by Isonicotinic Acid Hydrazide.** (Eng) Klamerth, O. L. (Institut fur Humangenetik, Universitat Heidelberg, D-69 Heidelberg, W. Germany). *Mutat Res* 50(2): 251-261; 1978.

The cell survival rate and mitotic index were determined in human peripheral lymphocytes exposed to various concentrations of isonicotinic acid hydrazide (INH) and N-methyl-N-nitrosourea (MNH), and the effect of INH on excision and postreplication repair in Chinese hamster ovary (CHO) cell cultures was determined. INH, in concentrations < 1 mM, was harmless to human cells. In the presence of MNU, however, even low concentrations of INH led to a pronounced reduction in cell survival and mitosis; this reduction was greater after 96 hr than after 72 hr. At > 5 mM, INH alone markedly depressed the cell number and the mitotic index. In CHO cells, incorporation of thymidine was almost totally inhibited by 10 mM INH, but up to 1 mM had no appreciable effect. No appreciable thymidine incorporation into the DNA of CHO cells, either with or without INH, was detected after treatment of these cells with NMU following blockage of normal semiconservative replication with hydroxyurea. A small increase over control value was consistently observed shortly after pulse labeling for MNU concentrations < 0.1 mM when semi-conservative replication was not inhibited. INH inhibited post-replication repair, possibly because it binds to exposed single-stranded segments of DNA in MNU-alkylated cells after strand breakage and/or excision of apurinic sites in parental DNA, followed by insertion into the daughter strand, but before sealing by ligase. INH had no effect on excision repair in these cells. (27 refs)

78-3161 **Dose Response to Intrarectal Administration of N-Methyl-N-nitrosourea and Histopathologic Evaluation of the Effect of Two Retinoids on Colon Lesions Induced in Rats.** (Eng) Ward, J. M. (Tumor Pathology Branch, Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, NIH, PHS, U.S. Dept. Health, Education and Welfare, Bethesda, MD, 20014); Sporn, M. B.; Wenk, M. L.; Smith, J. M.; Feeser, D.; Dean, R. J. *J Natl Cancer Inst* 60(6): 1489-1493; 1978.

Male F344 rats (8 wk of age) were given twice weekly intrarectal administrations of 2, 1, or 0.5 mg N-methyl-N-nitrosourea (NMU) for 8 wk. Five days after the last NMU instillation, the rats were placed on one of three diets: chow with gelatin beadlets, chow with beadlets containing 0.024% 13-cis-retinoic acid, or chow and beadlets with 0.006% of the trimethylmethoxyphenyl analog of retinoic acid ethylamide. Groups of rats were killed 22-26 wk after the first carcinogen treatment. The number of rats with colon carcinoma and the number of tumors per rat were dose-related. Tumors were noted in 75% of the high-dosed, 45% of the middle-dosed, and 25% of the low-dosed rats. Furthermore, pathologic investigation of four predesignated colon locations indicated a dose-related incidence of microscopic preinvasive and invasive colon carcinomas. The feeding of the different diets did not significantly alter tumor incidence or the mean histopathologic score at the predesignated locations for preinvasive or invasive neoplastic lesions. Over 90% of the colon tumors induced were invasive tubulopapillary adenocarcinomas. The diameters of the tumors correlated significantly with the degree of invasion of the colon. Only one tumor (a signet ring carcinoma) metastasized to the peritoneal cavity, and only 2/300 NMU-treated rats had tumors at sites other than the colon. (12 refs)

78-3162 **Mutagenicity of BCNU and Related Chloroethylnitrosoureas in Drosophila.** (Eng) Kortselius, M. J. (Dept. Radiation Genetics and Chemical Mutagenesis, Sylvius Labs., State Univ. Leiden, Wassensarseweg 72, Leiden, Netherlands). *Mutat Res* 57(3): 297-305; 1978.

To determine whether or not the mutagenicity of the chloroethylnitrosourea (CNU) group is influenced by N-1 substitutions, 1,3-bis(2-chloroethyl)-1-nitrosourea (BCNU) and 10 related CNU's were tested for their ability to induce sex-linked recessive lethals in mature Drosophila spermatozoa. All CNU's tested were found to be potent mutagens. Among the compounds with one CNU group, chlorozotocin, BCNU, and 1-(2-methanesulfonyloxyethyl)-3-(2-chloroethyl)-3-nitrosourea had the strongest mutagenic effects. Two hydroxyalkyl CNU's, CNU-ethanol [1-(ω-hydroxyethyl) -3- (2-chloroethyl)-3-nitrosourea] and CNU-propanol, also behaved as potent mutagens, although their mutation frequencies were one order of magnitude lower. Among the substances with two CNU groups, bisCNU-diphenylmethane [1,1-diphenylmethylenebis-3-(2-chloroethyl)-3-nitrosourea] and bisCNU-ethane were most active. When the interconnecting polymethylene chain was elongated from two (bisCNU-ethane) to six methylene groups (bisCNU-hexane), mutagenicity decreased by a factor of 2. The mutagenic activity of polymethylene bisCNU's with connecting chains of intermediate length was not different from that of bisCNU-hexane. The different mutagenic responses probably do not result from different reaction mechanisms for these compounds, but rather from differences in dose at the genetic target. Small structural changes in the nonmutagenic part of the molecules can result in differences in transportability, differences in actual doses at the target cells, and, thus, differences in mutagenicity. (25 refs)

78-3163 **Immunological Detection of O^6-Methylguanine in Alkylated DNA.** (Eng) Briscoe, W. T. (Dept. Biochemistry, School Medicine, Oral Roberts Univ., Tulsa, OK); Spizizen, J.; Tan, E. M. *Biochemistry* 17(10): 1896-1901; 1978.

Antibodies to O^6-methyldeoxyguanosine were produced in rabbits and used in a radioimmunoassay to detect this nucleoside at picomole levels. The specificity of the antibodies was demonstrated by the use of nucleoside analogs as inhibitors in the radioimmunoassay. The antibodies cross-reacted with O^6-methylguanosine, O^6-methylguanine, and O^6-ethylguanosine. There was 10^4-10^6 times less sensitivity to inhibition by deoxyadenosine, deoxyguanosine, and guanosine than by O^6-methyldeoxyguanosine. The radioimmunoassay also detected O^6-methylguanine in DNA alkylated by agents known to produce O^6-methylguanine, such as N'-methyl-N-nitrosourea. DNA alkylated with dimethyl sulfate, which does not produce O^6-methylguanine in DNA, cross-reacted with the antibodies to a very limited extent. Subsequent purification of the antibodies and further refinement of the assay system will enhance its sensitivity to a more practical level r use with biological systems. The system would be a useful ·obe for detecting O^6-methylguanine in DNA treated with :rtain alkylating agents, including carcinogens, and would so be useful in following the repair of such lesions. (26 refs)

3-3164 **Electron Spin Resonance Study of the Role of Nitrosyl-Heme in the Activation of Guanylate yclase by Nitrosoguanidine and Related Agonists.** (Eng) eRubertis, F. R. (Veterans Admin. Hosp., University Drive , Pittsburgh, PA); Craven, P. A.; Pratt, D. W. *Biochem iophys Res Commun* 83(1): 158-167; 1978.

artial purification of soluble guanylate cyclase (GC) from at liver results in loss of responsiveness of the enzyme to everal N-nitroso carcinogens, nitric oxide, nitrite, and nitrorusside (NP). Responsiveness to these agonists is restored y the addition of 0.25-50 μM of free or protein-bound heme lus a reducing agent, but not by other free or chelated forms f iron. The formation of nitrosyl-heme from the GC agonists I-methyl-N′-nitro-N-nitrosoguanidine (MNNG), NO, nirite, and NP was examined by electron spin resonance (ESR) pectroscopy under different incubation conditions and corelated with enzyme activation. The capacity of preformed itrosyl-Hb to stimulate partially purified enzyme activity 'as also assessed. In the presence of heme plus a reducing gent (1 mM dithiothreitol, cysteine, ascorbate, or glutathone), each enzyme agonist formed paramagnetic nitroyl-heme complexes, as shown by ESR spectroscopy. The apacity of MNNG, NO, nitrite, and NP to activate purified nzyme activity correlated with their capacity to generate itroso-heme under different incubation conditions. Preormed nitrosyl-Hb activated purified GC in the absence of oth heme and reducing agents, and max effects were noted t a concentration of 10 μM. It is concluded that nitroyl-heme is an active intermediate in the expression of the ctions of N-nitroso compounds, NO, nitrite, and NP on GC. 31 refs)

'8-3166 **Mechanisms of Inhibition by Ascorbate of Microbial Mutagenesis Induced by N-Nitroso Compounds.** (Eng) Guttenplan, J. B. (Dept. Biochemistry, New York Univ. Dental Center, New York, NY, 10010). *Cancer Res* 38(7): 2018-2022; 1978.

The effects of ascorbate on the mutagenesis induced in *Salmonella typhimurium* TA1530 by N-methyl-N′-nitro-N-nitrosoguanidine (MNNG), dimethylnitrosamine (DMN), and N-methyl-N-nitrosourea (MNU) were investigated. Ascorbate inhibited the mutagenesis induced by MNNG and DMN, but it had no effect on that induced by MNU. Inhibition of MNNG-induced mutagenesis resulted from a reaction between ascorbate and MNNG that led to consumption of MNNG. The rate of this reaction was considerably enhanced by catalytic amounts of Cu(II) and Fe(III). No direct reaction between DMN and ascorbate was detectable, but relatively high concentrations of Cu(II) enhanced the inhibition of DMN-induced mutagenesis by ascorbate. However, since DMN does not appear to be directly deactivated by ascorbate, a metabolite of DMN or even an activated oxygen species generated by the mixed-function oxidase system may be reduced by ascorbate. Added protein reduced the effectiveness of Cu(II) as a catalyst of the reaction between ascorbate and MNNG, suggesting that the microsomal protein necessary to activate DMN may reduce the concentration of free Cu(II) and thereby lower its catalytic efficiency. (18 refs)

78-3167 **In Vitro Transformation of Epidermal Cells from Newborn Mice.** (Eng) Slaga, T. J. (Biology Div., Oak Ridge Natl. Lab., P.O. Box Y, Oak Ridge, TN, 37830); Viaje, A.; Bracken, W. M.; Buty, S. G.; Miller, D. R.; Fischer, S. M.; Richter, C. K.; Dumont, J. N. *Cancer Res* 38(8): 2246-2252; 1978.

One-day-old primary cultures of epidermal cells from newborn BALB/c mice, plated at 10^6 cells/ml were treated for 2 days with various concentrations of N-methyl-N′-nitro-N-nitrosoguanidine (MNNG), 3-methylcholanthrene (3-MC), and 3-methylcholanthrene 11,12-epoxide (3-MC 11, 12-epoxide). Untreated newborn epidermal cells both divided and keratinized in vitro in Medium 199 supplemented with 10% fetal calf serum. After a few weeks the cells enlarged, showed signs of senescence, and then died after about 3 mo in vitro. The epidermal cells treated with MNNG, 3-MC, or 3-MC 11,12-epoxide went through a similar crisis, appearing as though they too were going to die at 3 mo. However, small populations of the remaining cells began to proliferate into colonies that soon grew to confluence. These epithelial cells were characterized by rapid growth, loss of visible keratinization, and subculturability, having been passaged 12 times, in contrast to untreated cells, which were not subculturable. Electron microscope studies did not reveal any true desmosomes, but junctional complexes were present in all cell strains examined. The injection of 10^6 cells from the epidermal cell strains into athymic 'nude' or syngeneic mice resulted in rapidly growing solid tumors that were characterized as highly anaplastic 'undifferentiated' tumors. (12 refs)

78-3168 **Induction and Isolation of Frameshift Mutants in Cultured Chinese Hamster Don Cells.** (Eng) Hamada, K. (Public Health Inst. Hyogo Prefecture, 2-1 Arata-cho, Hyogo-ku, Kobe 652, Japan); Isomura, K.; Teranishi, K.; Watanabe, H. *Mutat Res* 54(1): 61-72; 1978.

The induction, isolation, and characterization of frameshift [8-azaguanine-resistant (8-AG-r)] mutants induced in Chinese hamster Don (CHD) cells are reported. 2-Methoxy-6-chloro -9- [3-(2-chloroethyl)aminopropylamino] acridine dihydrochloride (ICR-191: 10^{-5} M) a potent frameshift mutagen, N-methyl-N′-nitrosoguanidine (MNNG: 5 x 10^{-6} and 10^{-6} M), and ethyl methanesulfonate (EMS: 2 and 3 x 10^{-2} M) increased the frequency of forward mutations from 8-AG sensitivity (8-AG-s) to 8-AG-r over controls significantly (approx 100-fold). Twenty-one 8-AG-r mutants were isolated from a CHD subline (AP-01 cells) after treatment with 10^{-5} and 1.36 x 10^{-5} M ICR-191, and several clonal mutants were tested for their ability to revert to 8-AG-s after treatment with the three mutagens and a carcinogen 2-nitrofluorene (2-NF), also a known frameshift mutagen. Clones ICR-014 and ICR-172 showed a significant increase in reversion frequency over control levels after treatment with ICR-191 and 2-NF, respectively, but not with the other two mutagens. These results suggest that these two mutants have a different frameshift mutation in one of the loci affecting 8-AG-r. Hypoxanthine-guanine phosphoribosyltransferase activities in clones ICR-014 and ICR-172 were 1.9% and 34% of that of the original AP-01 cells. (38 refs)

78-3169 Mutagenesis of Nitrosopiperidines in *Drosophila melanogaster* (Meeting Abstract). (Eng) Nix, C. E. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Brewen, B.; Wilkerson, R.; Epler, J. L. *Mutat Res* 53(1): 66-67; 1978. (1 ref)

78-3170 **Production of Pancreatic Acinar Cell Carcinoma by Combined Administration of 4-Hydroxyaminoquinoline 1-Oxide and Azaserine in Partial Pancreatectomized Rats.** (Eng) Konish, Y. (Dept. Oncological Pathology, Cancer Center, Nara Medical Univ., 840 Shijo-cho, Kashihara, Nara 634, Japan); Denda, A.; Inui, S.; Takahashi, S.; Ueda, N.; Namiki, M. *Cancer Lett* 4(4): 229-234; 1978.

The syncarcinogenic effect of azaserine (AS) and 4-hydroxyaminoquinoline 1-oxide (4-HAQO), as well as the influence of partial pancreatectomy, (PP) on the development of pancreatic carcinomas was studied in five groups of male Wistar rats. Group 1 had sham operation only; Group 2 had PP; Group 3 had 24 weekly injections of 5 mg/kg AS; Group 4 had PP and treatment as in Group 3 starting 3 days after the operation; Group 5 had PP, injection of 7 mg/kg
4-HAQO 3 days later, and then 10 weekly injectic
of 30 mg/kg AS. Groups 1, 2, and 5 were sacrific
at 52 wk. Groups 3 and 4 were sacrificed at 62 wk af
the initial carcinogen administration. No hyperplas
nodules, adenomas, or carcinomas were noted in
Group 1 or 10 Group 2 animals. Of 11 Group 3 anim
10 had hyperplastic nodules, 11 had adenomas, and 1 ha
a carcinoma. Of 14 Group 4 animals, 14 had hyperplast
nodules and adenomas, and 1 had a carcinoma. Of 10 Grou
5 animals, 5 had hyperplastic nodules, 10 had adenomas, an
7 had carcinomas. Liver metastases were noted in two Grou
5 animals. All carcinomas were acinar cell carcinomas th
invaded the surrounding tissue and vascular system. It is co
cluded that PP enhanced 4-HAQO carcinogenesis, which w
further promoted by AS. (9 refs)

78-3171 **The In Vitro Interaction of the Carcinogen
4-Nitroquinoline-N-oxide and Its Metaboli
4-Hydroxylaminoquinoline-N-oxide, with Intact Rat Liv
Mitochondria.** (Eng) Hadler, H. I. (Dept. Chemistry and Bi
chemistry, Southern Illinois Univ., Carbondale, IL, 62901
Cao, T. M. *Chem Biol Interact* 20(2): 219-226; 1978.

The interaction of 4-nitroquinoline N-oxide (NQO) and i
metabolite 4-hydroxylaminoquinoline-N-oxide (HAQ
with the mechanism of oxidative phosphorylation in mit
chondria derived from rat liver was investigated. When r
ducing equivalents were provided by the substrate β-hydro
ybutyrate and they flowed through the three coupling sit
of the respiratory chain, both NQO and HAQO (200 μM
acted as uncoupling agents. When β-hydroxybutyrate w
the substrate, NQO and HAQO caused reducing equivalen
to circumvent the first coupling sequence of the respirato
chain. With succinate as the substrate, the reducing equiv
lents flowed through coupling sites 2 and 3 of the respirato
chain. At 200 μM, NQO caused moderate uncoupling of t
second and third coupling sites of the respiratory chain.
contrast, 200 μM HAQO did not cause any uncoupling
sites 2 and 3 of the respiratory chain. Thus, NQO and HAQ
caused reducing equivalents to circumvent the first couplin
site of the respiratory chain. These results add to the expe
mental similarity between oxidative phosphorylation a
chemical carcinogenesis. (27 refs)

78-3172 **Distribution of 4-Nitroquinoline 1-Oxide R
ductase in the Mucosa of Canine Digesti
Tract.** (Eng) Suzuki, K. (Dept. Biochemistry, Nihon Uni
Sch. Medicine, 30-1, Ohyaguchi Kamimachi, Itabashi-k
Tokyo 173, Japan). *Gann* 69(2): 229-235; 1978.

The distribution of 4-nitroquinoline 1-oxide (4-NQO) redu
tase in the digestive tracts of mongrel dogs was studied. T
activity of the enzyme was highest in the esophagus (14
units) and next highest in the stomach (4.1 units). It w
much lower in the small and large intestines (< 1 unit) a

owest in the rectum (0.2 unit). The enzyme activity in the ipper portion of the esophagus was slightly higher than that n the middle and lower portions, it was significantly higher n the upper and middle portions of the female esophagus han in the same portions of the male esophagus. Only the nucous membrane of the esophagus showed a remarkably iigh enzyme activity, the activities in the tunica propria plus ubmucosa and tunica muscularis being low. 4-NQO reducase was detected in large amounts in the cytosol fraction of he esophageal mucous membrane and in small amounts in he microsome fraction. Uniform enzyme activity ranging rom 3.9 to 4.8 units was detected throughout the stomach: he greater and lesser curvatures, anterior and posterior parietes, and fundus; however, the activity was reduced by hree-fourths in the pyloric antrum. The enzyme activity was slightly higher in females than in males. (32 refs)

78-3173 **Metabolism of N-Nitrosomorpholine by the Rat In Vivo and by Rat Liver Microsomes and Its Oxidation by the Fenton System.** (Eng) Manson, D. (Chester Beatty Res. Inst., Inst. Cancer Res., Royal Cancer Hosp., Fulham Road, London SW3 6JB, England); Cox, P. J.; Jarman, M. *Chem Biol Interact* 20(3): 341-354; 1978.

N-Nitrosomorpholine was converted to N-nitroso-2-hydroxymorpholine by rat liver microsomes and by chemical oxidation in a modified Fenton system. The hydroxy derivative was also synthesized by the oxidation of N-nitrosodiethanolamine with permanganate and characterized as the methoxime and the 2,4-dinitrophenylhydrazone. The Fenton system also yielded products believed to be N-nitroso-2-morpholone and the 2-hydroperoxy- and 2-peroxyderivatives of N-nitrosomorpholine. The only urinary metabolite definitely identified was N-nitrosodiethanolamine. The significance of metabolic 2-hydroxylation in relation to the carcinogenic action of N-nitrosomorpholine is discussed. (30 refs)

78-3174 **Liver and Lung Tumors in Dogs from 4,4′-Methylene-bis(2-methylaniline).** (Eng) Stula, E. F. (Haskell Lab., Elkton Road, Newark, DE, 19711); Barnes, J. R.; Sherman, H.; Reinhardt, C. F.; Zapp, J. A. *J Environ Pathol Toxicol* 1(3): 339-356; 1978.

The occurrence of liver and lung tumors in dogs given 4,4′-methylene-bis(2-methylaniline) (MeMDA) is reported. Six female beagle dogs were given a daily po dose of 100 mg of MeMDA 3x/wk for 6 wk, then 5x/wk for 5 wk, at which time the dose was reduced to 50 mg 5x/wk and given continuously for periods ranging from 2.7 to 7.0 yr. Six female beagle dogs were kept as untreated controls and were sacrificed after 8.3-9 yr. The MeMDA-treated dogs developed renal atrophy with an elevated blood urea nitrogen during an approx 6-mo period prior to death or being sacrificed in extremis. Three of three MeMDA-treated dogs that survived 5.2-7.0 yr developed hepatocellular carcinomas, and two of these three also developed primary lung tumors. No liver or lung tumors were observed in the six control dogs. Four of the six control dogs had mammary tumors, but no such tumors were observed in the six MeMDA-treated dogs. The finding of mammary tumors in control dogs but not in MeMDA-treated dogs is most likely due to the difference in their ages rather than to an effect of MeMDA. It is concluded that MeMDA is carcinogenic for the dog at a probability level of $p < 0.05$ for liver tumors and $p < 0.10$ for lung tumors. (17 refs)

78-3175 **Mutagenicity of Styrene and Styrene Oxide.** (Eng) de Meester, C. (Lab. Analytical Chemistry, Univ. Louvain, Pharmacy Sch., UCL 7369 Brussels B-1200, Belgium); Poncelet, F.; Roberfroid, M.; Rondelet, J.; Mercier, M. *Mutat Res* 56(2): 147-152; 1977.

The mutagenicity of styrene and styrene oxide was examined in various *Salmonella typhimurium* strains with and without the S-9 fraction from Arochlor-induced male Wistar rats. In the absence of S-9, no direct mutagenic effect was observed for styrene at doses of 1 nanomole (nmol) to 100 micromoles (μmol) per plate. In the presence of the fraction, only strain TA1535 demonstrated his+ revertants; the number of revertants increased with doses of 1-11 μmol/plate. However, the higher dose was extremely toxic, with only 5% bacterial survival. At doses of 1 nmol to 100 μmol, styrene oxide was only mutagenic in TA1535 and TA100, both in the presence and absence of the S-9 mix. Toxicity was severe at doses $>$ 60 μmol/plate in the absence of the mix and at doses near 100 μmol/plate in the presence of the mix. These findings suggest that styrene is probably mutagenic, because it is metabolized to styrene oxide. (13 refs)

78-3176 **Deamination of 1-Methylcytosine by the Carcinogen N-Acetoxy-4-acetamidostilbene: Implications for Hydrocarbon Carcinogenesis (Letter to Editor).** (Eng) Scribner, J. D. (Pacific Northwest Res. Foundation, Seattle, WA, 98104); Smith, D. L.; McCloskey, J. A. *J Org Chem* 43(10): 2085-2087; 1978.

Reaction of the carcinogen N-acetoxy-4-acetamidostilbene with 1-methylcytosine in water and acetone resulted in a uracil derivative, apparently 1-(4-acetamidophenyl)-1-[3-(1-methyluracilyl)]-2-hydroxy-2-phenylethane. It is proposed that a similar reaction could take place between cytidine or a nucleic acid and a hydrocarbon epoxide. (11 refs)

78-3177 **Differential Mutagenicity of Reaction Products of Various Pyrazolones with Nitrite.** (Eng) Arisawa, M. (Dept. Microbiology and Chemotherapy, Nippon Roche Res. Center, 200 Kajiwara, Kamakura-247, Japan); Fujiu, M.; Suhara, Y.; Maruyama, H. B. *Mutat Res* 57(3): 287-296; 1978.

Four pyrazolones, antipyrine (AP), aminopyrine (AMP), sulpyrine (SP), and isopropylantipyrine (IPA), were compared with respect to their reactivity with sodium nitrite and the mutagenicity of their reaction products, as determined by the *Salmonella typhimurium* assay. Each pyrazolone (20 mg) was reacted with nitrite (40 mg) in 2 ml of water at pH 1.5-4.5 and incubated at 37 C. In the absence of nitrite, SP was unstable at these pH's and it degraded 50%-65%, but the other compounds were stable. The presence of nitrite, however, led to the complete degradation of AP, AMP, and SP within 1 hr. In contrast, IPA remained essentially intact. Dimethylnitrosamine was produced from AMP in 17%-79% yield, and 4-nitrosoantipyrine was produced from AP in 3%-22% yield. SP yielded at least five unidentified degradation products detectable by high-pressure liquid chromatography. Similar results were obtained at 0.1 mg/ml of the pyrazolones and equal or twofold amounts of nitrite. After lyophilization, the reaction products of AP were found to be mutagenic in *S. typhimurium* strains TA98 and TA100, but the products of AMP and SP were mutagenic only in TA100. In addition to SP, the products of AP and AMP contained several unidentified mutagens. Incubation with an S-9 mix prepared from activated rat liver microsomes did not affect the mutagenicity of the SP reaction products, but it decreased that of the products of AP and AMP. The IPA-nitrite reaction mixture was not mutagenic with either tester strain. Of the four compounds, only IPA appears safe with respect to possible mutagen formation by nitrite under physiological conditions. (6 refs)

78-3178 **Dehydroretronecine-induced Skin Tumors in Mice.** (Eng) Johnson, W. D. (Dept. Pathology, Univ. Wisconsin Medical Sch., Madison, WI, 53706); Robertson, K. A.; Pounds, J. G.; Allen, J. R. *J Natl Cancer Inst* 61(1): 85-89; 1978.

Female Swiss mice that are susceptible to skin tumors were given six sc injections and/or topical applications of dehydroretronecine (DR: 20 mg/kg), a metabolite of the pyrrolizidine alkaloid monocrotaline, and they were observed for tumor development over a 15-mo period. One or more tumors were observed in 63/92 treated mice, and 47/63 had skin tumors. Of the mice with skin tumors, 39/47 had basal cell carcinomas, 5/47 had squamous cell carcinomas, and one mouse each developed a single papilloma, mixed basosquamous carcinoma, and sebaceous adenoma. Three pulmonary adenocarcinomas also occurred. All of the non-skin tumors (except a rhabdomyosarcoma) were in areas distant from the site of DR application or injection. In contrast, most of the basal cell and squamous cell carcinomas developed at the site of injection or application and appeared as well-circumscribed, nonulcerating, sc nodules of varying sizes attached to the overlying epidermis. The results indicate that DR is a proximate carcinogen capable of causing a high inciden of skin tumors in mice at the site of sc injection or topic application. (25 refs)

78-3179 **Synthesis of the Urinary Glucuronic Acid Co jugate of N-Hydroxy-4-aminobiphenyl.** (En Moreno, H. R. (Dept. Pharmacology, Univ. Miami, Sc Medicine, Miami, FL, 33152); Radomski, J. L. *Cancer Le* 4(2): 85-88; 1978.

The glucuronic acid conjugate of N-hydroxy-4-aminobiph nyl was synthesized. The synthetic conjugate was identic by infrared and chromatographic analyses with the conjuga isolated from urine, thus establishing its structure as an N- conjugate, sodium (N,4- biphenyl -N- hydroxy-D-gl curonosylamine). (6 refs)

78-3180 **Activation of [^{14}C]Chlorobiphenyls to Pr tein-binding Metabolites by Rat Liver Mi crosomes.** (Eng) Hesse, S. (Gesellschaft f. Strahlen- und Um weltforschung, Abteilung fur Toxikologie, D-804 Neuherberg/Munich, W. Germany); Mezger, M.; Wolff, T *Chem Biol Interact* 20(3): 355-365; 1978.

The irreversible binding of ^{14}C-2,2′-di- and ^{14}C-2,4, 2′,4′,5′-hexachlorobiphenyl (^{14}C-DCB and ^{14}C-HC to protein was studied in the presence of Wistar r liver microsomes and an NADPH-generating syste Protein-bound radioactivity was found with ^{14}C-DC but not with ^{14}C-HCB. The binding of ^{14}C-metabolit was increased by pretreatment of the rats with phen barbital or polychlorinated biphenyls. Protein bindi was linear for 80 min. In contrast, monohydrox DCB metabolites were formed and degraded within 4 min. Inhibition of secondary oxidation of DCB by scavengin superoxide anions or by glucuronidation of the monopheno markedly decreased the protein binding. Addition of tr chloropropene oxide or styrene oxide, both inhibitors epoxide hydrase, did not significantly stimulate the bindin The results suggest that the majority of reactive DC metabolites arise from secondary metabolism, ie, the subs quent oxidation of the phenolic metabolites. Arene oxide the primary products, appear to play a minor role in th protein binding of DCB. (27 refs)

78-3181 **Epoxide Hydrase: Structure-Activity Relatio ships of In Vitro Stimulators of the Microsom Activity.** (Eng) Ganu, V. S. (Biology Div., Brookhaven Nat Lab., Upton, NY, 11973); Alworth, W. L. *Biochemistr* 17(14): 2876-2881; 1978.

The structure-activity relationships of several in vitr imulators of microsomal epoxide hydrase (EH) were studd using liver microsome preparations from male Sprae-Dawley rats. Benzophenone, 9-fluorenone, diphenylcyopropenone, benzyl phenyl ketone, propyl phenyl ketone, ialcone, and chalcone oxide (ChO) stimulated microsomal H in vitro, as measured by a standard radiometric assay ing styrene oxide as substrate. The most effective of these mpounds, ChO and 9-fluorenone, were more effective than etyrapone, a previously reported stimulator of this enzyme. ther aryl ketones, such as acetophenone, benzyl ethyl kene, dibenzyl ketone, and phenylmethylcyclopropenone, did ot stimulate EH activity. Kinetic analyses indicated that, though chalcone, 9-fluorenone, diphenylcyclopropenone, id ChO increased the Vmax of the EH reaction, diphenylcyopropenone and ChO increased the Vmax and Km by comrable factors. At higher concentrations of styrene oxide, ibstrate inhibition was observed. The kinetics of the mirosomal EH reaction with styrene oxide were consistent ith the formation of an inactive ES_2 (enzyme, $substrate_2$) omplex at high substrate concentrations. One in vitro effect ChO was to largely eliminate the inhibition caused by high yrene oxide concentrations. It is concluded that compounds ntaining an aryl carbonyl substituted with an additional ydrophobic group are effective in vitro stimulators of EH. he data suggest that these compounds bind at a site that is stinct from the catalytic site where styrene oxide binds. 8-3182 **Protein Composition of Nuclear Ribonucleoprotein Particles Isolated from Liver of Rats in ie Early Stages of Feeding of 3′-Methyl-4-dimethylninoazobenzene and from Hepatoma Induced by the ame Carcinogen.** (Eng) Patel, N. T. (Div. Biochemistry, ept. Human Biological Chemistry and Genetics, Univ. Texs Medical Branch, Galveston, TX, 77550); Holoubek, V. *hem Biol Interact* 19(3): 303-316; 1978.

he protein composition of liver nuclear 30S ribonucleorotein particles at three intervals after the start of feeding ′-methyl-4-dimethylaminoazobenzene (3′-MeDAB) or -aminoazobenzene (AB) to male albino Holtzmann rats was ompared with that of the same particles isolated from norial liver and from 3′-MeDAB-induced hepatoma. There ere no qualitative or quantitative differences in the polypepde composition of the core protein moiety of ribonucleorotein particles isolated from the liver of control rats, of nimals fed AB for 3, 6, or 10 wk, or of animals fed ′-MeDAB for 3 wk. The amount of the 42,000-dalton ore polypeptide was decreased after 6 wk of feeding ′-MeDAB and was completely missing after 10 wk. he loss of this polypeptide was not, however, characeristic of malignant transformation, since it was preent in an even higher proportion in nuclear ribonucleorotein particles isolated from 3′-MeDAB-induced epatomas than in particles isolated from control ver cells. 3′-MeDAB bound to the proteins of the liver nuclear ribonucleoprotein particles and interfered with RNA processing. Changes in the composition of the protein moiety of the particles could reflect changes in the liver cell population leading to the final selection of hepatoma cells that are resistant to the toxic effect of 3′-MeDAB on RNA processing. (32 refs)

78-3183 **Comparison of the Carcinogenicity and Immunologic Specificity of Aminoazo Compounds.** (Rus) Koresteleva, T. A. (Inst. Oncology, Leningrad, USSR); Potapenkova, L. S. *Gig Tr Prof Zabol* (5): 24-27; 1978.

The relationship between the carcinogenicity of aniline dyes and scission of their radical groups, known as haptens, was investigated. C3HA mice were fed the carcinogenic dye o-aminoazotoluene (AAT) or the structurally similar noncarcinogenic dye Scarlet R, 2 mg, for 60 to 100 days. Sera from these mice were assayed by Ouchterlony reaction using rabbit antisera containing antibodies to the AAT hapten. The sera of mice treated with AAT, but not those treated with Scarlet R, contained a carcinogenic metabolite that included a structural group of the carcinogen acting the part of the hapten. The data showed that antibodies against the AAT hapten had a high degree of specificity. Although Scarlet R contains the same radical group as AAT, this group was not separated from Scarlet R during the course of its metabolism in the mice. This indicates that aniline dyes that contain carcinogenic groups in their molecules may not be carcinogenic. (8 refs)

78-3184 **Tumor Induction by 7H-Dibenzo[c,g]carbazole in the Respiratory Tract of Syrian Hamsters.** (Eng) Sellakumar, A. (New York Univ. Medical Center, Inst. Environmental Medicine, Tuxedo, NY); Stenback, F.; Rowland, J.; Shubik, P. *J Toxicol Environ Health* 3(5-6): 935-939; 1977.

The carcinogenicity of the tobacco smoke component 7H-dibenzo[c,g]carbazole (DBC: particle size > 30 m) was investigated in Syrian golden hamsters. Group 1 received an intratracheal instillation of 3.0 mg DBC for 10 wk; Group 2 received 0.5 mg for 18 wk. Fifteen of 45 Group 1 animals developed a total of 21 respiratory tract tumors with a mean latency of 41 wk. These tumors were distributed among the larynx (1), trachea (11), bronchi (3), and lungs (5). Squamous cell carcinoma was the predominant tumor type found in the trachea, bronchi, and lungs. Thirty-three of 46 Group 2 animals developed respiratory tract tumors with a mean latency of 22 wk. There were 4 laryngeal, 22 tracheal, 15 bronchial, and 6 pulmonary tumors. Thirteen squamous cell carcinomas were found in the bronchi, 4 in the lungs; 21 tracheal papillomas were also identified. (11 refs)

78-3185 **In Vitro Chemical Carcinogenesis.** (Eng) Heidelberger, C. (Comprehensive Cancer Center, Los Angeles County-Univ. Southern California, Los Angeles, CA); Mondal, S. *In: Carcinogens: Identification and Mechanisms of Action. Proceedings of the Thirty-First Annual Symposium on Fundamental Cancer Research Held at Houston, Texas, 1-3 March 1978.* University of Texas System Cancer Center, M. D. Anderson Hospital and Tumor Institute, NCI, American Cancer Society. (Austin, Texas). 5 pp.; 1978. (no refs)

78-3186 **Analytical and Biological Analyses of Test Materials from the Synthetic Fuel Technologies. I. Mutagenicity of Crude Oils Determined by the *Salmonella typhimurium*/Microsomal Activation System.** (Eng) Epler, J. L. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Young, J. A.; Hardigree, A. A.; Rao, T. K.; Guerin, M. R.; Rubin, I. B.; Ho, C. H.; Clark, B. R. *Mutat Res* 57(3): 265-276; 1978.

The mutagenicity of crude industrial products and effluents was assayed with the Salmonella/microsomal activation system. The test materials (2 crude coal-liquefaction products and 2 natural crude oil samples) were fractionated into primary classes by liquid-liquid extraction and then further fractionated by column chromatography. Prescreening was accomplished over a wide concentration range with the tester strains TA1535, TA100, TA1537, TA1538, and TA98. All testing was carried out in the presence of rat liver microsome preparations from rats induced with either Arochlor 1259 or phenobarbital. Active fractions (mainly the neutral fractions containing polycyclic aromatic hydrocarbons and certain basic fractions) were identified, and dose-response relationships were established. Standard values (revertants/mg test material) were obtained with strain TA98. The total mutagenic activity of the two synthetic fuel samples was consistently higher than that of the natural crude oils. The activities of the subfractions were roughly additive, and they presumably reflected the mutagenic potential of the entire test material. There were several consistencies: (1) all crude and synthetic fuels showed some mutagenic potential, (2) the neutral and basic fractions showed activities regardless of source, and (3) the relative total mutagenic potentials varied over two orders of magnitude. The use of short-term biological test systems coupled with analytical chemical evaluation of complex materials encountered in modern technology may provide basic information for predicting and identifying biohazards for human populations. (18 refs)

78-3187 **Anthracene-induced Melanotic Tumors in *Drosophila*.** (Eng) Corwin, H. O. (Dept. Life Sciences, Univ. Pittsburgh, Pittsburgh, PA, 15260); Gottlieb, F. J. *Environ Res* 15(3): 327-331; 1978.

The possible genetic and teratogenic effects of low level chronic exposure to anthracene, dibenz(a,h)anthracene, benzo(a)pyrene, and pyridine were assayed in *Drosophil melanogaster*. Chronic exposure was accomplished by feedin the Drosophila three different low concentratio (10^{-3}, 10^{-4}, or 10^{-5} M) of individual agents throughout their larval development. Differences in surviv to the adult stage between control and treated fli were taken as signs of immediate toxic effects. Th surviving adults were examined for tumors an developmental abnormalities and mated according to several designs. None of the four agents induced a significan frequency of X-linked mutations detectable by multigeneration tests. The F_1 progeny of anthracene-treated males an females had a significant frequency of melanotic tumor production. No such significant tumor-forming activity was obvious in the F_1 and F_2 progenies from parents treated wit the remaining three agents. Although all three concentration of anthracene induced tumor production, there was n clear-cut indication of a dose response. It is concluded tha the increase in tumor production, that results from anthracene treatment is probably due to the induction of transmissible, dominant mutations having low penetrance. (4 refs)

78-3188 **Determination of Arene Oxides by a Ga Chromatography-Mass Spectrometry System Thermal Reactions of 9,10-Epoxy-9,10-dihydrophenanthrene.** (Eng) Patel, J. R. (Center Bio-Organic Studies, Univ. New Orleans, Lakefront, New Orleans, LA, 70122); Griffin, G. W.; Laseter, J. L. *Anal Lett* B11(3): 239-247; 1978.

An analytical technique in which a gas chromatograph is coupled to a mass spectrometer-computer system was developed to detect arene oxides using 9,10-epoxy-9,10-dihydrophenanthrene as a model substrate. With this technique, both deoxygenation and rearrangement of the model substrate were observed. Reactants and products were identified by comparing the retention times and mass spectral fragmentation patterns of authentic samples. (13 refs)

78-3189 **Inducible DNA Polymerase in Cultured Rat Fibroblasts Treated with Skin Carcinogen Mitomycin C.** (Eng) Bozhkov, V. M. (Inst. Cytology, Acad. Sciences USSR, Leningrad 190121, USSR); Barskaya, T. V.; Fridlyanskyaya, I. I.; Tomilin, N. V. *FEBS Lett* 86(2): 205-208; 1978.

The origin and reaction properties of the DNA polymerase in rat fibroblasts treated with mitomycin C were investigated. MMC treatment resulted in a two-fold increase of DNA polymerase with DNAa or DNAd as template. However, with the template initiator pdA·odT, activity decreased significantly after MMC treatment. Addition of the protein synthesis inhibitor puromycin (PM) completely blocked the rise in DNA-dependent DNA polymerase activity produced by

IMC. Cycloheximide produced similar results, suggesting iat the increase in DNA-dependent activity after MMC eatment is due to the translation of newly formed or preexting mRNAs'. No differences in the sensitivity of constituve and MMC-induced activities to variations in ion concenations (K^+, Na^+, Mg^{2+}, Mn^{2+}) were observed in andard assays with a DNAa template. Spermidine did not ffect MMC-induced DNAa-dependent activity, but it did ihibit the constitutive activity by 30%-35%. This finding as reversed in the assay with DNAd. There was also a diference between the inducible and constitutive DNA polymeases in the rate of incorporation of incorrect precursor leoxycytidine triphosphate) into pdA·odT modified by -bromomethylbenzanthracene. It is concluded that treatent of rat fibroblasts with MMC results in the suppression f constitutive DNAd-polymerase(s) and the synthesis of nother DNAa polymerase with a higher affinity for primer NA and a lower fidelity. (23 refs)

8-3190 **Carcinogenicity and Mutagenicity of Benz(a)anthracene Diols and Diol-Epoxides.** Eng) Slaga, T. J. (Biology Div., Oak Ridge Natl. Lab., Oak idge, TN, 37830); Huberman, E.; Selkirk, J. K.; Harvey, .; Bracken, W. M. *Cancer Res* 38(6): 1699-1704; 1978.

he carcinogenicity of benz(a)anthracene (BA), its five possile trans-dihydrodiols, and five of its diol-epoxides was invesgated following topical application to female CD-1 mice. he mutagenicity of BA and the trans-dihydrodiols was evaated in Chinese hamster V79 cells cocultivated with iradiated golden hamster embryo cells to metabolize the comounds. In the mutagenicity studies, (±)-trans-3,4 ihydroxy -3,4- dihydrobenz(a)anthracene (BA, ,4-dihydrodiol) was approx 10 times more mutagenic than A and about 20 times more mutagenic than the other dihyrodiols. However, it was much less (> 100 times) mutagenic ian benzo(a)pyrene, which was tested for comparison purposes. In the skin tumor-initiating experiments, all BA comounds were applied in a single dose of 2 micromoles, and ach treatment was followed 1 wk later by twice weekly aplications of 10 μg 12-O-tetradecanoylphorbol-13-acetate for 6 wk. BA 3,4-dihydrodiol was approx five times more active ian BA as a tumor initiator; the other BA hydrodiols were ll less active. (±)-trans- 3α,4β-Dihydroxy- 1-γ,2γ-epoxy-,2,3,4-tetrahydro-benzo(a)anthracene was approx 20% iore active as a tumor initiator than BA 3,4-dihydrodiol; the ther diol-epoxides were less active than BA. These findings iggest that the bay-region diol-epoxide of BA may be the ltimate carcinogenic and mutagenic form of BA. (41 refs)

3-3191 **Effect of Fetal Tissue on Experimental (7,12-Dimethylbenz[α]anthracene) Breast ancer in Rats.** (Eng) Reichle, F. A. (Dept. Surgery, emple Univ. Health Sciences Center, Philadelphia, PA, 19140); Noval, J. J.; Obando, M.; Rao, N.; Ryzlak, M. T.; Reichle, R. M. *J Surg Res* 24(6): 563-569; 1978.

The effect of treatment with small quantities of Sprague-Dawley (Holtzman) rat fetal tissue on mammary tumor development was studied in 8-wk-old syngeneic females given a single intragastric instillation of 7,12-dimethylbenz(a)anthracene (DMBA: 10 mg in 1 ml sesame oil). Each rat received two injections of live or dead fetal tissue suspensions (1 g/10 ml) given at the same time: 0.2 ml sc and 0.1 ml ip. The live tissue suspension contained 60%-70% living cells; the dead tissue had been killed by freeze-thawing and homogenization. The dead tissue homogenates were administered weekly for 3 wk prior to and/or after DMBA or for 5 wk starting at the time of DMBA administration. The live tissue suspensions were administered according to the 5-wk schedule. Treatment with dead fetal tissue significantly accelerated the appearance of the DMBA-induced tumors, but treatment with live tissue greatly suppressed tumor development and caused a high rate of tumor regression. Only 1/7 rats given five weekly injections of live tissue had a palpable tumor at 15 wk and, in this group, only eight tumors were found at autopsy at 26 wk. In another experiment, breast tumor development was not altered by live or dead fetal tissue inoculated 2 wk before DMBA treatment. These results are discussed in terms of host immunologic reactions. (23 refs)

78-3192 **The Effect of Levamisole on Experimental Carcinogenesis of Rat Submandibular Gland.** (Eng) Pisanty, S. (Dept. Oral Medicine and Oral Pathology, Harvard Sch. Dental Medicine, Boston, MA, 02115); Eisenberg, E.; Shklar, G. *Arch Oral Biol* 23(2): 131-135; 1978.

The effect of levamisole, a nonspecific enhancer of cellular immunity, on the development of 9,10-dimethyl-1,2-benzanthracene (DMBA)-induced submandibular gland tumors was studied in four groups of male albino rats, 30 or 60 days old. Group 1 animals (10) received a DMBA pellet implanted in the right submandibular gland, and they were inoculated sc with 0.6 mg/day levamisole on three consecutive days every 2 wk. Group 2 animals (10) received DMBA implants but no levamisole. Groups 3 and 4 were levamisole-treated and untreated controls. Although DMBA induced epidermoid carcinomas in both Groups 1 and 2, the tumors developed approx 3 wk later in the Group 1 animals. In addition, the tumors in this group were less anaplastic and less invasive than those in Group 2. Age had no apparent effect on the carcinogenic process. (24 refs)

78-3193 **Species-specific Cellular DNA-binding Proteins Expressed in Mouse Cells Transformed by Chemical Carcinogens.** (Eng) Sen, A. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD, 20014); Todaro, G. J. *Proc Natl Acad Sci USA* 75(4): 1647-1651; 1978.

Mouse cells transformed by DNA and RNA tumor viruses and by chemical carcinogens were examined for the presence of specific DNA-binding proteins by DNA-cellulose chromatography. Using mouse DNA-cellulose, single-stranded DNA-binding proteins were obtained from two clones of BALB/3T3 cells transformed by the chemical carcinogens dimethylbenzanthracene (DMBA) and methylcholanthrene. Simian virus 40 transformants also had a DNA-binding protein, ie, the viral tumor (T) antigen, that bound to mouse and human DNA with comparable affinity. Kirsten or Moloney sarcoma virus-transformed cells and two other clones transformed by DMBA or benzo(a)pyrene showed no difference in DNA-binding protein pattern, compared with the untransformed parental cell. The DNA-binding proteins isolated from the chemically transformed cell clones were between 25,000 and 30,000 daltons by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. These cellular T proteins bound to the homologous mouse cellular DNA with a higher affinity than to heterologous human cellular DNA. (26 refs)

78-3194 **Formation of 7,12-Dimethylbenz[a]Anthracene-DNA Adducts in 7,8-Benzoflavone-treated Hamster Embryo Cells.** (Eng) Baird, W. M. (Wistar Inst. Anatomy and Biology, 36th St. at Spruce, Philadelphia, PA, 19104); Diamond, L. *Chem Biol Interact* 20(2): 181-190; 1978.

The effects of pretreating secondary cultures of Syrian hamster embryo cells with 7,8-benzoflavone (7,8-BF), a potent inhibitor of the mixed-function oxidase enzyme system, on the metabolism of 7,12-dimethylbenz(a)anthracene (DMBA) and the formation of DMBA-DNA adducts were determined. 7,8-BF pretreatment [0.25, 0.5, or 1.0 nanomole (nmol)/ml] inhibited both the metabolism of DMBA (0.5 nmol/ml) and the formation of adducts. The DMBA-deoxyribonucleoside adducts from 7,8-BF-treated cultures had the same elution profiles on Sephadex LH-20 columns as those from cultures exposed to DMBA alone, but 7,8-BF-treated cultures contained smaller amounts of DMBA-DNA adducts per milligram of DNA. With increasing 7,8-BF concentrations, the decrease in the amount of DMBA-DNA adducts per milligram of DNA was logarithmic with respect to the decrease in the amount of DMBA metabolized. These findings suggest that more than one metabolic step is required for the binding of DMBA to DNA in hamster embryo cells. (31 refs)

78-3195 **Inhibition of Polycyclic Aromatic Hydrocarbon-induced Neoplasia by Naturally Occurring Indoles.** (Eng) Wattenberg, L. W. (Dept. Lab. Medicine and Pathology, Univ. Minnesota, Minneapolis, MN, 55455); Loub, W. D. *Cancer Res* 38(5): 1410-1413; 1978.

The effects of indole-3-carbinol, 3,3′-diindolylmethane, and indole-3-acetonitrile on 7,12-dimethylbenz(a)anthrace (DMBA)-induced mammary tumors in female Sprague-Dav ley rats and on benzo(a)pyrene (BP)-induced forestomach tumors in female ICR/Ha mice were investigated. These i doles occur in edible cruciferous vegetables such as brusse sprouts, cabbage, cauliflower, and broccoli. DMBA was a ministered by po intubation at a dose of 12 mg; BP was a ministered by po intubation in 1-mg doses 2 x/wk for 4 w or in 0.3-mg doses 3 x/wk for 8 wk. When given by po intuba tion 20 hr prior to DMBA administration, indole-3-carbin and 3,3′-diindolylmethane inhibited mammary tumor forma tion; indole-3-acetonitrile was inactive. Indole-3-carbinol ad ded to the diet for 8 days prior to DMBA challenge inhibite mammary tumor formation but indole-3-acetonitrile did no Dietary administration of all three indoles inhibite BP-induced forestomach neoplasia. (26 refs)

78-3196 **Separation of Two Forms of Cytochrome P-45 From Hepatic Microsomes of 1,2,3,4-Dibenzanthracene (DBA)-Pretreated Little Skates (*Raja erinacea*) (Meeting Abstract).** (Eng) Elmamlouk, T. H. (Marine Pharmacology and Biomedicine Section, Lab. Pharmacology NIEHS, Research Triangle Park, NC, 27709); Philpot, R M.; Bend, J. R. *Environ Health Perspect* 20: 229; 1977. (n refs.)

78-3197 **Ultrastructure and Biological Markers of Neoplastic Change in Adult Mouse Epithelial Cells Transformed In Vitro.** (Eng) Knowles, M. A. (Dept. Cellula Pathology, Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Franks, L. M. *Br J Cancer* 37(4): 603-611; 1978.

The ultrastructure and biological markers indicative of neoplastic change in five in vitro-transformed mouse submandibular gland epithelial cell lines were determined. Four of these lines had been transformed by 24 hr treatment with 0.1 μg/ml 7,12-dimethylbenz(a)anthracene; the fifth was isolated from a dimethyl sulfoxide-treated culture. In vitro acinus formation occurred in all lines, and well-differentiated epithelial cells showing epithelial microvilli, desmosomes, and cytoplasmic tonofilaments were present. None of the cells showed the specific ultrastructural features of normal differentiated submandibular gland ducts. All lines formed colonies in semisolid agar and on confluent monolayers of BALB/c 3T3 cells, and all lacked density-dependent inhibition of growth, as demonstrated by a random distribution of thymidine labeling throughout growing cultures. These three growth properties appear to be reliable in vitro markers for epithelial neoplastic transformation in this system; however, colony-forming efficiency in agar was lower than that reported for many transformed mesenchymal cells. (28 refs)

8-3198 **Interindividual Variation in the Responses of Cultured Human Lymphocytes to Exposure rom DNA Damaging Chemical Agents. Interindividual ariation to Carcinogen Exposure.** (Eng) Pero, R. W. (Wal- enberg Lab., Nucleic Acid Biochemistry, Univ. Lund, Fack 031, S-220 07 Lund 7, Sweden); Bryngelsson, C.; Mitelman, .; Kornfalt, R.; Thulin, T.; Norden, A. *Mutat Res* 53(3): 27-341; 1978.

ndividual variations in the in vitro response of human lym- hocytes to N-acetoxy-2-acetylaminofluorene (NA-AAF) nd 7,12-dimethylbenz(a)anthracene (DMBA) were deter- nined by measuring (1) the differential stimulation of un- cheduled DNA synthesis after 1 hr exposure to 10 μM NA-AAF, (2) the level of NA-AAF-induced chromosome berrations remaining after 8 hr of DNA repair synthesis, nd (3) the level of ^{3}H-DMBA bound to DNA after 18 hr ncubation of resting lymphocytes in 5 μM DMBA. Lym- hocytes from 92 men, 90 women, and 20 children were used. ll three parameters indicated that there were individual ariations in the response of lymphocytes to the carcinogens, nd they were correlated with population differences in age, ex, blood pressure, and mortality rates. Males had a greater otential to accumulate DNA damage than females, regard- ess of the sampled population. DNA damage potentials in- reased with increasing age, blood pressure, or mortality ates. The in vitro response of mature granulocytes to a 10- μM NA-AAF dose, as estimated by ^{3}H-thymidine incorpora- ion from unscheduled DNA synthesis, was much lower than he lymphocyte response. Nevertheless, individual variations n granulocyte NA-AAF-induced unscheduled DNA synthe- is paralleled the interindividual fluctuations observed in ymphocyte responses to NA-AAF. (37 refs)

8-3199 **Formation of Free Radicals from Carcinogenic Benz[c]acridines in the Presence of Proteins.** Eng) Okano, T. (Pharmaceutical Inst., Aobayama, Sendai 80, Japan); Horie, T.; Iwaizumi, M.; Motohashi, N. *Gann* 9(1): 109-114; 1978.

he formation of free radicals from carcinogenic and noncar- inogenic benz[c]acridine (BCA) derivatives was studied in he presence of proteins. The noncarcinogenic compounds vere BCA, 11-methyl-BCA, and 9-methyl-BCA; the carcino- enic compounds were 7-methyl-BCA, 7,11-dimethyl-BCA, ,9-dimethyl-BCA, 7,10-dimethyl-BCA, and 7,9,10-trimeth- l-BCA. When mixtures of the BCAs and protein were tirred for long periods and shielded from light, the BCA's vere converted into free radicals. Bovine serum albumin had he greatest effect on accelerating free-radical formation; a maller effect was noted with globulin, histone, and DNase. he g value of the free radicals thus obtained was 2.005. The ntensity of the electron spin resonance (ESR) signals of the ree radicals from carcinogenic derivatives was higher than hat of the free radicals from noncarcinogenic derivatives. here was a correlation between the ESR signal intensity of he free radicals, the charge of the K-region or ring nitrogen of the BCA's, and the carcinogenicity of the BCA's. These findings suggest that free radicals are important in BCA carcinogenesis. (17 refs)

78-3200 **Induction of Antibodies Against Carcinogenic Polycyclic Aromatic Hydrocarbons.** (Eng) Moolten, F. L. (Boston Univ. Sch. Medicine, 80 E. Concord St., Boston, MA, 02118); Capparell, N. J.; Boger, E.; Mahathalang, P. *Nature* 272(5654): 614-616; 1978.

Studies were conducted on the feasibility of inducing antibodies against carcinogenic polycyclic aromatic hydrocarbons (PAH) using an analog of the PAH carcinogen dimethylbenzanthracene (DMBA) substituted with a fluorine moiety to abrogate carcinogenicity. The DMBA analog, 5-fluoro-12-methylbenzanthryl-7-acetic acid (FMBAAA), was nontoxic, did not induce tumors in C57Bl/6J mice, and was nonmutagenic in the Ames bacterial mutagenesis assay. Guinea pigs immunized with GMBAAA yielded antisera capable of binding FMBAAA and also DMBA. One serum was also able to bind to benzo(a)pyrene (BP) and benzo(rst)pentaphene. No binding was observed with the nonaromatic polycyclic compound cholic acid. When globulin fractions from these sera were tested in an in vitro cytotoxicity assay using hamster embryo cells, the antisera completely abrogated the toxicity of 0.01 μg DMBA and greatly reduced the toxicity of 0.05 μg DMBA. The ability of mice immunized with FMBAAA to excrete fed ^{3}H-BP as γ-globulin-bound complexes was significantly higher than that of unimmunized controls. Extrapolation of these data to humans suggests the feasibility of inducing antibody levels capable of binding, and perhaps neutralizing, carcinogens present in the environment in low, but not high, concentrations. (19 refs)

78-3201 **AHH Activity Induced by DMBA and its Binding to DNA of Mammary Cells in Organ Culture (Meeting Abstract).** (Eng) Telang, N. T. (Tumor Biology Lab., Univ. Nebraska, Lincoln, NB, 68588); Kundu, A. B.; Banerjee, M. R. *In Vitro* 14(4): 337; 1978. (no refs)

78-3202 **Steroid Metabolism in the Normal Mammary Gland and in the Dimethylbenzanthracene-induced Mammary Tumor of Rats.** (Eng) Mori, M. (Natl. Inst. Radiological Sciences, 9-1, Anagawa-4-Chome, Chiba-shi 280, Japan); Tominaga, T.; Tamaoki, B. *Endocrinology* 102(5): 1387-1397; 1978.

The in vitro metabolism of progesterone by female Sprague-Dawley rat normal mammary glands and mammary tumors induced by 9,10-dimethyl-1,2-benzanthracene (DMBA; 25 mg/kg, iv) was determined. Following incubation of ^{14}C-progesterone with cell-free homogenates of tumor tissue, 20α-hydroxy-4-pregnen-3-one, 5α-pregnane-3,20-dione, 20α-hydroxy-5α-pregnan-3-one, 3α-hydroxy-5α-pregnan-20-one, and 5α-pregnane-3α,20α-diol were identified as the metabolites. In normal mammary tissue, however, 4-pregnene-3α,20α-diol was isolated in addition to 5α-reduced and 3α- and 20α-hydroxy metabolites. When labeled testosterone was used as a substrate, 5α-dihydrotestosterone and 5α-androstane-3α,17β-diol were the metabolites of the mammary tumor. In the normal mammary gland, only 4-androstene-3α,17β-diol was formed. Although the enzyme activities relevant to the metabolism varied among the tumors examined, the activity of 20α-hydroxysteroid dehydrogenase in the mammary tumor was significantly lower than that in the normal gland. However, the activity of 5α-reductase was higher in some of the mammary tumors than in the normal gland. The 5α-reductase activity in the normal gland was mostly localized in the crude microsomal fraction, but the same enzyme activity in the tumor was detected in all the organelle fractions. The activities of 20α-hydroxysteroid dehydrogenase and NADPH-linked 3α-hydroxysteroid dehydrogenase activities were found mainly in the cytosol fractions of the tumor and normal tissue. The latter was detected only in the cytosol fraction of the normal gland, but was detected in all subcellular fractions of the tumor that were examined. (38 refs)

78-3203 **Cyclic Adenosine 3′,5′-Monophosphate-Binding Protein: Role in Ovariectomy-induced Regression of a Hormone-Dependent Mammary Tumor in Sprague-Dawley Female Rats: Brief Communication.** (Eng) Cho-Chung, Y. S. (Lab. Pathophysiology, NCI, NIH, Public Health Service, U.S. Dept. Health, Education, and Welfare, Bethesda, MD, 20014); Bodwin, J. S.; Clair, T. *J Natl Cancer Inst* 60(5): 1175-1178; 1978.

The relationship between cyclic AMP- and estrogen-binding activities was investigated in 7,12-dimethylbenz(a)anthracene-induced mammary carcinomas in Sprague-Dawley rats during tumor growth and regression following ovariectomy. Within 3 days after ovariectomy, cyclic AMP binding increased markedly and estrogen binding decreased in regressing tumors. These changes were reversed when tumor growth was resumed following the sc injection of estradiol-17β. The data suggest the possible involvement of cyclic AMP binding in the growth control of a hormone-dependent mammary tumor. (26 refs)

78-3204 **Lack of Tumor-promoting Ability of Certain Environmental Chemicals in a Two-Stage Mouse Skin Tumorigenesis Assay.** (Eng) Berry, D. L. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); DiGiovanni, J.; Juchau, M. R.; Bracken, W. M.; Gleason, G. L.; Slaga, T. J. *Res Commun Chem Pathol Pharmacol* 20(1): 101-108; 1978.

Butylated hydroxytoluene (BHT), butylated hydroxyanisole (BHA), Aroclor 1254 (polychlorinated biphenyl, PCB), Firemaster-6 (polybrominated biphenyl, PBB), and 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) were tested on CD1 female mice for their tumor-promoting ability following application of 0.2 ml of a 200-nanomole soln of 7,12-dimethylbenz(a)anthracene (DMBA). At a dose of 1 mg twice weekly, neither BHT nor BHA promoted skin tumors; no tumors were induced when they were tested for carcinogenicity without DMBA initiation. PCB and PBB, at a dose of 100 μg twice weekly after DMBA application, were also inactive as promotors. TCDD was tested at a dose of 0.1 μg twice weekly; it did not promote DMBA-induced tumors and did not act as a carcinogen by itself. It did, however, result in skin rashes. None of the compounds significantly increased the intrafollicular epidermis. If the doses of the compounds were increased to levels that would lead to epidermal proliferation, their toxicity would interfere with the carcinogenic response prior to termination of the test. These results indicate that dosage may be an important factor in promotion, since some of these compounds are promotors in pulmonary and hepatic systems. (22 refs)

78-3205 **The Bacterial Mutation Test.** (Eng) Anderson, D. (No Affiliation Given); Styles, J. A. *Br J Cancer* 37(6): 924-930; 1978.

The Ames bacterial-mutation test was evaluated for its ability to screen organic chemicals for potential carcinogenicity. Four strains of *Salmonella typhimurium* (TA1535, TA1538, TA98, and TA100) were exposed to a total of 120 chemicals. The highest mean number of revertants at any dose was used to assess carcinogenic potential. The overall accuracy of the test in predicting carcinogenicity was 91% for carcinogens and 94% for noncarcinogens, indicating that the Salmonella mutation system is useful for predicting the carcinogenicity of organic chemicals. Many compounds (eg, 2-aminoanthracene, 6-aminochrysene, 2-naphthylamine, and 4-aminobiphenyl) were not specific in the type of mutation they caused; ie, they were not specifically base-pair or frameshift mutagens. No attempt was made to rank the chemicals in order of carcinogenic potency on the basis of mutagenic activity. (14 refs)

78-3206 **The Identification of 3-Methylcholanthrene-9,10-dihydrodiol as an Intermediate in the Binding of 3-Methylcholanthrene to DNA in Cells in**

Culture. (Eng) King, H. W. (Chemical Carcinogenesis Div., Inst. Cancer Res., Pollards Wood Res. Station, Nightingales Lane, Chalfont St. Giles, Buckinghamshire HP8 4SP, England); Osborne, M. R.; Brookes, P. *Chem Biol Interact* 20(3): 367-371; 1978.

Two 3-methylcholanthrene (3MC) metabolites, previously shown to be precursors of the DNA-bound form of 3MC observed in cultured embryo cells, were prepared by microsomal metabolism and isolated by high-pressure liquid chromatography (HPLC). From HPLC and mass spectrometric analyses of the metabolites and from comparison with the fluorescence spectra of the five possible dihydrodiols of alkylated benzanthracene, it was inferred that one of the metabolites was 1- or 2-hydroxy-3MC-9,10-dihydrodiol and the other, 3MC-9,10-dihydrodiol. (5 refs)

78-3207 **Genetic Variation in Metabolism of Chemical Carcinogens Associated with Susceptibility to Tumorigenesis.** (Eng) Nebert, D. W. (Developmental Pharmacology Branch, Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD); Levitt, R. C.; Pelkonen, O. *In: Carcinogens: Identification and Mechanisms of Action. Proceedings of the Thirty-First Annual Symposium on Fundamental Cancer Research Held at Houston, Texas, 1-3 March 1978.* University of Texas System Cancer Center, M. D. 78-3208 **Mouse-Strain Difference in Immunoprophylactic and Immunotherapeutic Effects of BCG on Carcinogen-induced Autochthonous Tumors.** (Eng) Tokunaga, T. (Dept. Tuberculosis, Natl. Inst. Health, Shinagawa-ku, Tokyo 141, Japan); Yamamoto, S.; Nakamura, R. M.; Kurosawa, A.; Murohashi, T. *Jpn J Med Sci Biol* 31(2): 143-154; 1978.

The immunoprophylactic and immunotherapeutic effects of BCG on 3-methylcholanthrene (3-MC)-induced tumors were compared in female Swiss-derived SWM/Ms and C3H/He mice. One group of each strain was treated with 5 x 10^7 viable units of BCG id 2 wk before 3-MC (0.5 mg sc), and one group received 3-MC only (controls). In C3H mice, the first tumors appeared 5 wk after 3-MC injection. The number of tumor bearers increased rapidly from 8 to 11 wk, and at 20 wk, tumor incidence was nearly 100% in both groups. In SWM mice, the first tumor appeared at 8 wk, and tumor incidence at 30 wk was approx 80% and 90% in the SWM-BCG and control groups, respectively. The number of tumor bearers increased more slowly in the former. Differences in tumor incidence between the two SWM groups were significant at 9-12, 14, and 18 wk after 3-MC. However, once the tumors were established, they grew progressively and killed the hosts of both strains. Intratumor injection of BCG into nodules > 5 mm in diameter in all tumor bearers resulted in tumor regression or retardation or prolongation of survival time in most SWM-BCG mice, but not in C3H mice. Some SWM controls experienced tumor retardation. It was noted that 4/171 C3H-BCG and 7/35 SWM-BCG mice, but none of the controls, died within 2 wk after BCG injection. A peritoneal macrophage disappearance test and a footpad reaction test showed that C3H and SWM mice have different host responses to BCG: C3H mice are low responders, and SWM mice are high responders. It is not known whether the high tumor incidence in C3H mice is linked with low responsiveness to BCG and/or histocompatibility. The results indicate that the host immune response to BCG is a critical factor in BCG antitumor activity. (25 refs)

78-3209 **Fluorescence Study of DNA-binding Metabolites of Benzo(a)pyrene Formed in Hepatocytes Isolated from 3-Methylcholanthrene-treated Rats.** (Eng) Jernstrom, B. (Dept. Forensic Medicine, Karolinska Institutet, S-104 Stockholm 60, Sweden); Orrenius, S.; Undeman, O.; Graslund, A.; Ehrenberg, A. *Cancer Res* 38(8): 2600-2607; 1978.

Hepatocytes and liver microsomes isolated from 3-methylcholanthrene-treated Sprague-Dawley rats metabolized benzo(a)pyrene (BP) to products that bound to endogenous DNA and exogenous calf thymus DNA, respectively. By a sensitive fluorescence technique, it was possible to characterize the major DNA-binding metabolite in hepatocytes as being produced by further metabolism of 9-hydroxybenzo(a)pyrene (9-OH-BP). In microsomes, two products binding to calf thymus DNA were recovered, a major species formed by activation of 9-OH-BP and a minor fraction formed by further metabolism of 7,8-dihydro-7,8-dihydroxybenzo(a)pyrene (BP 7,8-dihydrodiol). The available evidence indicates that the ultimate products responsible for binding to DNA were identical to 9-OH-BP 4,5-oxide and BP 7,8-dihydrodiol 9,10-oxide, respectively. The data further suggest that metabolic activation of 9-OH-BP results in the quite different DNA:metabolite complexes. The former product(s) seems to be strongly associated with hydrophobic regions in DNA, but the latter metabolite(s) appears to be more exposed to the exterior. (45 refs)

78-3210 **Inducibility of Activation and/or Detoxication Enzymes in Benzo(a)pyrene Metabolism by 3-Methylcholanthrene.** (Eng) Nemoto, N. (Dept. Experimental Pathology, Cancer Inst., 1-37-1, Kami-Ikebukuro, Toshima-ku, Tokyo 170, Japan); Takayama, S. *Toxicol Lett* 1(5/6): 247-252; 1978.

The inducibility of hepatic aryl hydrocarbon hydroxylase (AHH) and two conjugating enzymes, uridine diphosphate-glucuronyltransferase (UDP-G) and sulfotransferase (ST), by 3-methylcholanthrene (MC) was investigated in several strains of mice and rats. There are various types of conjugation in benzo(a)pyrene (BP) metabolism, and the extent of these conjugations is considered to play an important role in the carcinogenicity of BP. The experimental animals were given a single ip injection of 80 mg/kg MC and then killed 24 hr later. UDP-G and ST activities were determined using 3-OH-BP as substrate. Of the five inbred strains, C57BL/6, C3H/He, and BALB/c mice (responsive strains) had increased AHH activity following MC treatment, but DBA/2 and AKR mice (nonresponsive strains) did not. UDP-G and ST activities were not altered in all five strains. Wistar and ACI rats and ICR/JCL mice, which were produced by closed-colony mating, were responsive to AHH and UDP-G induction by MC; their ST activity was not affected. Thus, in some species and strains, induction of AHH and UDP-G may be regulated in parallel. (29 refs)

78-3211 **Comparative Incorporation of Uridine-^{3}H into Nucleolar RNA of Mouse Subcutaneous and Skin Tissues at Early Times after 20-Methylcholanthrene Administration.** (Eng) Gulati, P. K. (Dept. Biophysics, Panjab Univ., Chandigarh-160014, India); Dubey, D. P. *Experientia* 34(3): 396-397; 1978.

^{3}H-Uridine uptake by the nucleolar RNA of the skin and sc tissues was investigated in 55 C57BL/Bcr female mice after they were inoculated with a single carcinogen dose of 20-methylcholanthrene (20-mc: 1 mg in 0.2 ml olive oil sc). Treated mice were given an ip injection of ^{3}H-uridine (6μ Ci/g) and decapitated 2 hr later. ^{3}H-Uridine incorporation into the nucleolar RNA of the skin and sc tissue around the injection site was increased 17 and 3 times, respectively, 24 hr after 20-mc injection. The uptake was normal at 37 hr after carcinogen injection. The functional significance of these changes has not been established, but they may indicate the importance of nucleolar function in the carcinogenic process. (7 refs.)

78-3212 **Carcinogenesis in Immunologically Privileged Sites.** (Eng) Ziegler, M. M. (Dept. Surgery, Univ. Pennsylvania, Philadelphia, PA, 19104); Barker, C. F. *Fed Proc* 37(7): 2057-2058; 1978.

Hamsters were treated with 3-methylcholanthrene (3-MC) either topically, by subepithelial injection, or by subepithelial implantation to determine whether de novo chemical induction of tumors might be easily achieved in sites where immunological surveillance is impaired. Of nine animals receiving topical applications of 10 mg/ml 3-MC to ear skin inlaid in autografted cheek pouches, seven developed papillomas after 11-116 days (mean, 48 days). Similar treatment of seven hamsters with vehicle only resulted in only one tumor. When 3-MC was applied to the autografted cheek pouch itself, 3/5 animals developed tumors. Dye experiments indicated that the cheek pouch and inlaid ear skin in these animals had impaired lymphatic drainage. In sites of normal lymphatic drainage (ear skin autografted to trunk skin), 0/13 animals treated with 3-MC developed tumors. Fibrosarcomas developed in 8/8 hamsters inoculated with 0.8-1.6 mg 3-MC in autografted cheek pouches after 28-169 (mean 121 days). Subepithelia in the trunk area of nine animals produced tumors in only two, with latent periods of 240 and 316 days. When filter paper impregnated with 5% 3-MC was subepithelially implanted in cheek implants of five hamsters, two developed tumors. Of four animals receiving implantations in areas of normal lymphatics, three developed tumors. The mean peripheral WBC count in eight normal hamsters was 4,431/mm^3; this increased to 6,843/mm^3 after a dose of 2 mg 3-MC and 7,733/mm^3 after 3 mg 3-MC. Topical administration of 3-MC for 17 consecutive days did not change the median survival time of MHA hamster skin grafts on LHC hamsters from that of untreated control LHC animals. These findings support the theory that tumor formation is more likely when immunity is impaired. (10 refs)

78-3213 **Carcinogenetic Process in Experimental Squamous Cell Carcinoma in Canine Lungs.** (Jpn) Hayata, Y. (Dept. Surgery, Tokyo Medical Coll., Skinjuku-ku, Tokyo 160, Japan); Kato, H.; Chow, M. C.; Tachibana, M.; Hayashi, N.; Tawara, M.; Kawauchi, T.; Seo, Y.; Amemiya, R. *Nippon Kyobu Shikkan Gakkai Zassh* 15(11): 759-768; 1977.

Carcinogenesis was studied in two adult beagles and four adult mongrel dogs given an injection of 50 mg 20-methylcholanthrene at the bifurcation of the apical and cardiac bronchi every 7 days. Proliferation of the basal cells accompanied by the appearance of atypical nuclei or nuclear division was noted immediately after injection; these cells were replaced by metaplastic cells after 1 wk. All dogs exhibited mildly atypical squamous cell metaplasia after 1-4 wk and moderately atypical squamous cell metaplasia after 2-8 wk. Severely atypical squamous cell metaplasia was noted in four dogs 5-9 wk after the beginning of treatment, and three dogs developed carcinoma in situ between 8 and 14 wk. Invasive carcinoma developed after 18-22 wk in three dogs. These findings suggest that squamous cell metaplasia is an important precursor of squamous cell carcinoma. (20 refs)

78-3214 **Prostaglandin Synthetase Dependent Activation of 7,8-Dihydro-7,8-dihydroxy-benzo(a)pyrene to Mutagenic Derivatives.** (Eng) Marnett, L. J. (Dept. Chemistry, Wayne State Univ., Detroit, MI, 48202); Reed, G. A.; Dennison, D. J. *Biochem Biophys Res Commun* 82(1): 210-216; 1978.

The *Salmonella typhimurium* tester strain TA98 was used to study the prostaglandin synthetase-dependent production of mutagenic derivatives from benzo(a)pyrene (BP) and its dihydrodiol metabolites. There was no increase in the reversion rate of TA98 following incubation with BP in the presence of prostaglandin synthetase and arachidonic acid, and the presence of the bacteria did not affect the oxidation of BP to quinones. Thus, the lack of mutagenicity was not due to an inhibition of prostaglandin synthetase-dependent BP oxidation by the bacterial preparation. The addition of BP-7,8-diol, but not BP-4,5-diol or BP-9,10-diol, to the assay system resulted in a > 10-fold increase in the number of revertants. The activation of BP-7,8-diol was markedly reduced by the omission of arachidonic acid, and inhibited by the prostaglandin synthetase inhibitor indomethacin, and it exhibited a dose-response relationship with respect to the diol. Inclusion of 100 μM of the antioxidant butylated hydroxyanisole in the assay mixture inhibited by 89% the increase in the number of revertants induced by BP-7,8-diol. The data suggest that during prostaglandin biosynthesis, BP-7,8-diol was cooxidized to a BP-diol epoxide, although it is possible that BP-7,8-diol was activated by a unique pathway to strongly mutagenic derivatives that were not diol epoxides. (20 refs)

78-3215 **Metabolism of trans-9,10-Dihydroxy-9,10-dihydrobenzo(a)pyrene Occurs Primarily by Arylhydroxylation Rather than Formation of a Diol Epoxide.** (Eng) Thakker, D. R. (Section Oxidative Mechanisms, Lab. Chemistry, Natl. Inst. Arthritis, Metabolism, and Digestive Diseases, NIH, Bethesda, MD, 20014); Yagi, H.; Lehr, R. E.; Levin, W.; Buening, M.; Lu, A. Y.; Chang, R. L.; Wood, A. W.; Conney, A. H.; Jerina, D. M. *Mol Pharmacol* 14(3): 502-513; 1978.

The oxidative metabolism of trans-9,10-dihydroxy-9,10-dihydrobenzo(a)pyrene was investigated in vitro using microsomal protein preparations from 3-methylcholanthrene-treated Long-Evans rats to determine whether 9,10-diol 7,8-epoxides are formed, and the mutagenic activities of synthetic benzo(a)pyrene (BP) 9,10-diol 7,8-epoxide derivatives were evaluated. Unlike BP 7,8-dihydrodiol, the trans-9,10-dihydrodiol was metabolized primarily to a phenolic derivative rather than a diol epoxide. Chemical and spectral studies established that the phenolic hydroxyl group had been introduced at either position 1 or 3 of the 9,10-dihydrodiol. The weak inherent mutagenic activity of the synthetic 9,10-diol 7,8-epoxides and the very low degree of their metabolic formation explain why metabolic activation of BP 9,10-dihydrodiol in the presence of *Salmonella typhimurium* resulted in a weak mutagenic response compared with studies using the 7,8-dihydrodiol as substrate. Chronic application of 0.15 micromole of BP 9,10-dihydrodiol to the backs of C57BL/6J mice once every 2 wk for 60 wk failed to produce tumors, but the same treatment with BP resulted in a 97% tumor incidence. (37 refs)

78-3216 **Metabolism of Benzo(a)pyrene in Animals with High Aryl Hydrocarbon Hydroxylase Levels and High Rates of Spontaneous Cancer.** (Eng) Busbee, D. L. (Dept. Biology, North Texas State Univ., Denton, TX, 76203); Guyden, J.; Kingston, T.; Rose, F. L.; Cantrell, E. T. *Cancer Lett* 4(2): 61-67; 1978.

Aryl hydrocarbon hydroxylase (AHH) induction and benzo(a)pyrene (BP) metabolism were studied in salamanders (*Ambystoma tigrinum*) removed from a sewage-polluted pond, a population of animals with a high level of spontaneous tumors. Some of these animals were analyzed immediately for AHH content, and others were placed in clean, aerated water. Salamanders that had been maintained in the laboratory were induced with a single ip injection of 3-methylcholanthrane (MC; 10 mg/kg). Animals taken directly from the pond were found to have hepatic microsomal AHH levels about 80% as high as those of animals inoculated with MC. After animals were held in clean water for several months, their AHH levels were as low as those of control untreated laboratory salamanders. Microsomes from the salamanders were reacted with BP, and the metabolites were separated by high-pressure liquid chromatography. BP metabolites produced by salamander liver microsomes were qualitatively similar to those reported for mammals; however, the percentage of the metabolites appeared to differ significantly. Treatment of induced salamander microsomes with cyclohexene oxide or 1,2-epoxy-3,3,3-trichloropropane during incubation significantly changed the metabolic profile. The greatest effect was decreased diol production, indicating a normal epoxide hydrase conversion of intermediate compounds to the diol form. These findings suggest that an inducing agent is present in relatively high concentrations in the polluted water, and that a correlation appears to exist between high AHH induction, the presence of polycyclic hydrocarbon pollutants, and the high spontaneous cancer rate in salamanders. (25 refs)

78-3217 **Molecular and Cellular Events Associated with the Action of Initiating Carcinogens and Tumor Promoters.** (Eng) Weinstein, I. B. (Inst. Cancer Res. and Div. Environmental Science, Columbia Univ., New York, NY). *In: Carcinogens: Identification and Mechanisms of Action. Proceedings of the Thirty-First Annual Symposium on Fundamental Cancer Research Held at Houston, Texas, 1-3 March 1978.* University of Texas System Cancer Center, M. D. Anderson Hospital and Tumor Institute, NCI, American Cancer Society. (Austin, Texas). 27-28 pp.; 1978. (no refs)

78-3218 **Properties of Aryl Hydrocarbon (Benzo[a]Pyrene) Hydroxylase in Lung Microsomes of Mice.** (Eng) Watanabe, M. (Res. Inst. Tuberculosis and Cancer, Tohoku Univ., Seiryo-machi 4-1, Sendai 980, Japan); Konno, K.; Sato, H. *Gann* 69(1): 1-8; 1978.

The effects of a single po dose of 1 mg/kg benzo(a)pyrene

(BP) or a single ip dose of 1 mg/kg 3-methylcholanthrene (MC) on aryl hydrocarbon hydroxylase activity in C3H/He and DBA/2 mouse lung were determined. Regardless of animal strain, BP increased AHH activity in the lung, but not in the liver, of treated mice. However, AHH activity was increased in the intestine and skin of C3H/He mice but not DBA/2 mice. Comparison of the properties of enzymes induced by MC with the constitutive enzymes in animals treated with corn oil only indicated that the two enzymes had similar pH activity curves and similar apparent Km for NADPH and NADH. However, the constitutive enzyme had a higher Km for BP (25 μM) than the induced enzyme (6 μM). 5,6-Benzoflavone, 7,8-benzoflavone, and 2,2′-bipyridine inhibited the activity of the two enzymes similarly, but N-benzyl-N,α-dimethylphenethylamine hydrochloride and 2-diethylaminoethyl diphenylpropylacetate inhibited the activity of the constitutive enzyme more severely than that of the induced enzyme. Cyclohexene oxide, 1,1,1-trichloropropane oxide, and leupeptin slightly inhibited the activity of the constitutive enzyme, but enhanced the activity of the induced enzyme. The significance of these differences to the carcinogenicity of polycyclic hydrocarbons is discussed briefly. (36 refs)

78-3219 **Formation of DNA-binding Products from Isolated Benzo[α]pyrene Metabolites in Rat Liver Nuclei.** (Eng) Jernstrom, B. (Dept. Forensic Medicine, Karolinska Institutet, S-104 01 Stockholm 60, Sweden); Vadi, H.; Orrenius, S. *Chem Biol Interact* 20(3): 311-321; 1978.

Benzo(a)pyrene (BP) or one of its metabolites (30 μM) was incubated with isolated liver nuclei from 3-methylcholanthrene-treated rats, and the reaction products were analyzed by high-pressure liquid chromatography. In the presence of NADPH, the liver nuclei metabolized 3- and 9-hydroxy-BP (3-OH-BP, 9-OH-BP) and 7,8-dihydro-7,8-dihydroxy-BP (BP 7,8-dihydrodiol) to products that bound to DNA. Max binding was obtained with BP 7,8-dihydrodiol as substrate. This binding was 10, 3, and 60 times higher than that occurring after incubation with BP, 9-OH-BP, and 3-OH-BP, respectively. Both 4,5-dihydro-4,5-dihydroxy-BP and 9,10-dihydro-9,10-dihydroxy-BP were also metabolized extensively by the nuclear fraction, but they did not give rise to DNA-binding products. It is concluded that the DNA-binding species derived from 9-OH-BP is 9-OH-BP 4,5-oxide and the species derived from BP 7,8-dihydrodiol is BP-7,8-dihydrodiol 9,10 oxide. (28 refs)

78-3220 **Studies on the Metabolism and Excretion of Benzo(a)pyrene in Isolated Adult Rat Hepatocytes.** (Eng) Jones, C. A. (Dept. Biochemistry, Univ. Surrey, Guildford, Surrey, GU2 5XH, England); Moore, B. P.; Cohen, G. M.; Fry, J. R.; Bridges, J. W. *Biochem Pharmacol* 27(5): 693-702; 1978.

Hepatocytes from male albino Wistar rats were isolated and used to study the metabolism of benzo(a)pyrene (BP), with particular attention being focused on the fate of the metabolites. BP was metabolized to both ethyl acetate-soluble and water-soluble metabolites. The former cochromatographed with 4,5-dihydro-4,5-dihydroxyBP, 7,8-dihydro-7,8-dihydroxyBP, 9,10-dihydro-9,10-dihydroxyBP, and 3-hydroxyBP and its sulfate ester, benzo(a)pyren-3-yl-hydrogen sulfate. Hydrolysis of the water-soluble metabolites with β-glucuronidase released ethyl acetate-soluble metabolites that cochromatographed with 7,8-dihydro-7,8-dihydroxyBP, 4,5-dihydro-4,5-dihydroxyBP, 9,10-dihydroxyBP, and 3-hydroxyBP. Initially, incubation resulted in only ethyl acetate-soluble metabolites that were partially released into the medium; with continued incubation, water-soluble metabolites were produced and released from the cells. The individual ethyl-acetate soluble metabolites showed significant distributional differences: monohydroxyBPs and (to a lesser extent) the sulfate esters of monohydroxyBPs accumulated intracellularly, 4,5-dihydro-4,5-dihydroxyBP and 7,8-dihydro-7,8-dihydroxyBP were fairly evenly distributed between the cells and the medium, and 9,10-dihydro-9,10-dihydroxyBP was found mainly in the medium. Significant radioactivity from labeled BP was irreversibly bound to cellular macromolecules. (33 refs)

78-3221 **Characteristics of Benzo(a)pyrene Metabolism and Cytochrome P-450 Heterogeneity in Rat Liver Nuclear Envelope and Comparison to Microsomal Membrane.** (Eng) Fahl, W. E. (Dept. Pharmacology, Univ. Wisconsin Medical Sch., Madison, WI, 53706); Jefcoate, C. R.; Kasper, C. B. *J Biol Chem* 253(9): 3106-3113; 1978.

Benzo(a)pyrene (BP) metabolism was compared in Holtzman rat liver nuclear envelopes and microsomes. The formation of BP metabolites was extremely low in the nuclear envelopes and, unlike the microsomes, it was not induced by phenobarbital (PB) pretreatment. However, after 3-methylcholanthrene pretreatment (3-MC), the metabolism increased more in the nuclear envelopes (60 times) than in the microsomes (5.5 times). Thus, the specific activities per nanomole of cytochrome P-450 equalized. Although the product distribution was similar in nuclear envelopes and microsomal membranes, a decrease in dihydrodiols and an increase in phenols were observed in the nuclear envelopes. 3-MC resulted in a 13-fold increase in BP 7,8-dihydrodiol metabolism in the nuclear envelope, and it favored the formation of the anti diol-oxide stereoisomer. Nuclear epoxide hydratase activity was not induced by 3-MC or by PB, which increased the enzyme activity threefold in the microsomes. NADPH-cytochrome c reductase was also induced only in the microsomes. Four separate forms of cytochrome P-450 were identifiable in the nuclear envelope by their type I difference spectra. PB markedly affected the levels of the individual nuclear cytochrome P-450 species without producing a net increase. In contrast, 3-MC doubled the net nuclear envelope cytochrome P-450 content, shifting the absorbance max to 448 nanometers. The absence of a microsomal, camphor-binding cytochrome P-450 species in nuclear envelope preparations indicated insignificant microsomal contamination (< 1%). (44 refs)

78-3222 **Effect of Bile Acids and Neutral Sterols on Benzo[a]pyrene-induced Tumorigenesis in Skin of Mice: Brief Communication.** (Eng) Watanabe, K. (Dept. Surgery, Akita Univ. Sch. Medicine, Akita, Japan); Narisawa, T.; Wong, C. Q.; Weisburger, J. H. *J Natl Cancer Inst* 60(6): 1501-1503; 1978.

A series of experiments was conducted to determine whether neutral sterols and bile acids are cocarcinogenic on female Swiss Ha:ICR mouse skin when applied together with benzo(a)pyrene (BP). A soln of 5 μg BP and 1 mg of the bile acid or sterol (except lithocholic acid, which was applied at a dose of 0.5 mg because of its low solubility) was applied thrice weekly to the skin of the mice for 60 wk. The animals were killed 63 wk after initiation of the experiment. Most of the chemicals had an inhibitory effect on skin tumor formation by BP. Unconjugated bile acids had higher inhibitory action than did conjugated bile acids. The inhibition decreased in the following order of acids: chenodeoxycholic, lithocholic, deoxycholic, and cholic. Within the group of conjugated acids, taurine conjugates were more effective inhibitors than were glycine conjugates. The neutral sterols cholesterol, coprostanol, and coprostanone showed moderately inhibitory effects on BP carcinogenesis. (23 refs)

78-3223 **Mutagenicity to Mammalian Cells in Culture by (+) and (-) trans-7,8-Dihydroxy-7,8-dihydrobenzo(a)pyrenes and the Hydrolysis and Reduction Products of Two Stereoisomeric Benzo(a)pyrene 7,8-Diol-9,10-epoxides.** (Eng) Huberman, E. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Yang, S. K.; McCourt, D. W.; Gelboin, H. V. *Cancer Lett* 4(1): 35-43; 1978.

The mutagenicity of benzo(a)pyrene (BP) and nine of its derivatives was tested by ouabain resistance in Chinese hamster V79 cells, which were derived from a subclone of V79-4 cells. The nine derivatives included the (+) and (-) enantiomers of trans-7,8-diol; (±)trans-7,8-diol; (7/8,9)-triol; (7,9/8)-triol; (7,10/8,9)-tetrol; (7/8,9,10)-tetrol; (7,9/8,10)-tetrol; and (7,9,10/8)-tetrol. Since V79 cells do not metabolize polycyclic hydrocarbons (they do not contain detectable mixed-function oxidase), tests were made in the presence and absence of golden hamster cells, which are capable of metabolizing polycyclic hydrocarbons. None of the compounds were mutagenic for V79 cells alone at concentrations up to about 3 μM. In the presence of golden hamster cells, however, BP and the three trans-7,8-diols were cytotoxic and mutagenic, and the mutagenic response increased as a function of hydrocarbon concentration. At an equal concentration of 0.4 μM, the (-)trans-7,8-diol was about 65% more active than the (±)trans-7,8-diol, about 6 times more active than the (+)trans-7,8-diol, and 10 times more active as a mutagen than BP. All other derivatives were inactive. (39 refs)

78-3224 **DNA and RNA Adducts Formed in Hamster Embryo Cell Cultures Exposed to Benzo(a)pyrene.** (Eng) Ivanovic, V. (Inst. Cancer Res., Coll. Physicians and Surgeons, Columbia Univ., New York, NY, 10032); Geacintov, N. E.; Yamasaki, H.; Weinstein, I. B. *Biochemistry* 17(9): 1597-1603; 1978.

The time course of the covalent binding of ^{14}C-benzo(a)pyrene (BP) to RNA and DNA in hamster embryo cell cultures and the types of nucleoside adducts were investigated. Binding to RNA proceeded rapidly, and it followed a linear time course for at least 48 hr. In contrast, the extent of binding to DNA reached a plateau after approx 18 hr of incubation with ^{14}C-BP. Fluorescence spectroscopy of the modified nucleic acids and high-pressure liquid chromatography of the nucleoside adducts provided evidence that benzo(a)pyrene-7,8-dihydrodiol 9,10-oxide (BPDE) is the major BP metabolite responsible for the covalent modification of hamster embryo cellular nucleic acids. Both BPDE I and II isomers were synthesized and both participated in the modification of the host RNA and DNA. Although guanine was the major BPDE target during in vivo modification of RNA and DNA, there was a low but detectable modification of adenine and cytosine bases. The relative contributions of the various BPDE isomers to in vivo nucleic acid modification varied between DNA and RNA. The types of RNA adducts did not depend on the length of exposure to BP. In contrast, the relative amounts of the multiple types of DNA adducts changed with time, suggesting that they underwent differential rates of excision. The heterogeneity of the DNA adducts in primary hamster embryo cell cultures was greater than that observed in previous studies with human and bovine bronchial explants exposed to BP. Possible differences in DNA-BPDE adducts among species and cell types are discussed. (29 refs)

78-3225 **Postreplication Repair of DNA in Human Fibroblasts after UV Irradiation or Treatment with Metabolites of Benzo(a)pyrene.** (Eng) Waters, R. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Yagi, H.; Jerina, D. M.; Regan, J. D. *Chem Biol Interact* 20(3): 289-297; 1978.

The ability of normal fibroblasts and of excision-deficient xeroderma pigmentosum (XP) and XP variant fibroblasts to perform postreplication DNA repair after increasing doses of either UV radiation or mutagenic benzo(a)pyrene (BP) derivatives was examined. The cells were exposed to UV at doses of 10, 20, and 30 joules/m^2 and to BP 7,8-diol-9,10-epoxide derivatives at the following doses: 5 x 10^{-7} and 10^{-6} M of the trans-diastereomer and 2 x 10^{-6} M of the *cis*-diastereomer. XP cells defective in the excision of both UV-induced pyrimidine dimers and guanine adducts induced by treatment with the BP 7,8-diol-9,10-epoxides were partially defective in their ability to synthesize high-mol wt DNA after the induction of both classes of DNA lesions. The defect was more marked in XP variant cells, despite their ability to remove by excision repair both pyrimidine dimers and the diol epoxide-induced lesions to the same extent as normal cells. Similar amounts of BP 9,10-oxide had no effect in any of the three cell lines. The response of the excision and postreplication DNA repair mechanisms operating in human fibroblasts treated with BP 7,8-diol-9,10-epoxides, therefore, appears to resemble closely that seen after the induction of pyrimidine dimers by UV irradiation. (21 refs)

78-3226 **Repair of DNA Damaged by Mutagenic Metabolites of Benzo(a)pyrene in Human Cells.** (Eng) Regan, J. D. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Francis, A. A.; Dunn, W. C.; Hernandez, O.; Yagi, H.; Jerina, D. M. *Chem Biol Interact* 20(3): 279-287; 1978.

The repair of human skin fibroblast DNA after damage by known and potential benzo(a)pyrene (BP) metabolites was examined in the bromodeoxyuridine photolysis assay. The type of repair was classified as long (UV damage) or short (ionizing radiation damage) using normal cells and cells deficient in UV repair endonuclease from a xeroderma pigmentosum patient. Only (±)-7β,8α-dihydroxy-9β,10β-epoxy-7,8,9,10-tetrahydro-BP (BP diol epoxide 1) and its diastereomer (±) -7β,8α- dihydroxy -9α,10α- epoxy-7,8,9,10-tetrahydro-BP (BP diol epoxide 2) elicited DNA damage recognizable by the UV excision repair system in normal human cells. BP 4,5-, 9,10-, and 11,12-oxides did not elicit damage repairable by this system. Naphthalene 1,2-diol-3,4-epoxides had no measurable activity in the assay. These results indicate that both the BP ring structure and the diol epoxide groups are important in causing the DNA damage that is repairable by the long excision repair system. These results parallel the reported high mutagenic activity of these compounds and thus support the concept that the BP 7,8-diol-9,10-epoxides may be the ultimate, metabolically activated forms of BP. (29 refs)

78-3227 **Human Bronchus-mediated Mutagenesis of Mammalian Cells by Carcinogenic Polynuclear Aromatic Hydrocarbons.** (Eng) Hsu, I. C. (Bethesda, MD, 20014); Stoner, G. D.; Autrup, H.; Trump, B. F.; Selkirk, J. K.; Harris, C. C. *Proc Natl Acad Sci USA* 75(4): 2003-2007; 1978.

Cultured human bronchial explants from 13 subjects activated benzo(a)pyrene (BP) to electrophilic metabolites that bound to DNA in bronchial epithelial cells. Promutagenic and mutagenic BP metabolites were also released into the culture medium. An increase in mutation frequency for ouabain resistance was found in Chinese hamster V-79 cells cocultivated with the bronchial explants in the presence of BP. The proximate carcinogenic form of BP, the 7,8 diol [(±)-r7,t8-dihydroxy-7,8-dihydrobenzo(a)pyrene] was five times more potent as a promutagen than th parent compound. Neither BP nor the 7,8-diol increase the mutation frequency of V-79 cells cultured withou bronchial explants. The mutation frequency was directl related to the binding levels of BP to bronchial DNA and the concentration of BP or the 7,8-diol in th medium. (28 refs)

78-3228 **Cyclopenta(c,d)pyrene: A Highly Mutagenic Polycyclic Aromatic Hydrocarbon.** (Eng) Eisenstadt, E. (Dept. Microbiology, Harvard Sch. Public Health, Boston, MA, 02115); Gold, A. *Proc Natl Acad Sci USA* 75(4): 1667-1669; 1978.

Cyclopenta(c,d)pyrene (CPP), recently identified as a component of carbon black, automobile exhaust, and atmospheric soot, was tested for mutagenicity with histidine auxotrophs of *Salmonella typhimurium*. In the presence of a rat liver microsome activation system, CPP was highly mutagenic for *S. typhimurium* strains TA98, TA100, TA1537, and TA1538. The CPP mutagenicity levels were comparable to those of benzo(a)pyrene and dibenz(a,c)anthracene. The potent mutagenicity of CPP is noteworthy because it is a polycyclic aromatic hydrocarbon without a bay region and it is distributed widely in the environment. On the basis of experimental observations and perturbational molecular orbital calculations, it is proposed that the mutagenic metabolite of CPP is the 3,4-oxide. The carbonium ion derived from the opening of CPP 3,4-oxide is identical to that derived from the opening of benzo(a)pyrene 7,8-diol-9,10-oxide, the metabolite now thought to be an ultimate mutagenic and carcinogenic species. 78-3230 **Induction of Epidermal Cell Proliferation by a Tumour Promoter in Vitamin B$_6$-deficient**

Mice. (Eng) Murray, A. W. (Sch. Biological Sciences, Flinders Univ. S. Australia, Bedford Park, S. Australia 5042, Australia). *Experientia* 34(6): 691; 1978.

The effect of decreased induction of ornithine decarboxylase, caused by a vitamin B_6-deficient diet, on the ability of 12-O-tetradecanoylphorbol-13-acetate (TPA) to enhance the proliferative activity of mouse epidermal cells was studied. Female Swiss albino mice were maintained for 14 days on a complete or a vitamin B-deficient diet. Animals were treated with TPA (17 nanomoles in 0.2 ml acetone) and, at varying times after treatment, with 0.1 mg colchicine ip 2 hr before sacrifice. TPA induced a marked proliferative response in the epidermis of mice maintained on both the complete and vitamin B_6-deficient diets. The mitotic indices for both groups did not differ significantly. These data do not support a causal relationship between ornithine decarboxylase and induction of proliferative activity in mouse epidermis. (10 refs)

78-3231 **Metabolic Conversion of 12-O-Tetradecanoylphorbol-13-acetate in Adult and Newborn Mouse Skin and Mouse Liver Microsomes.** (Eng) Berry, D. L. (Biology Div., Oak Ridge Natl. Lab., P.O. Box Y, Oak Ridge, TN, 37830); Bracken, W. M.; Fischer, S. M.; Viaje, A.; Slaga, T. J. *Cancer Res* 38(8): 2301-2306; 1978.

Tritiated 12-O-tetradecanoylphorbol-13-acetate was applied to adult female CD-1 mouse skin. At specified time intervals, the mice were killed, and the labeled phorbol was extracted and subjected to separation and quantitation by high-pressure liquid chromatography. After 24 hr, TPA comprised $> 96\%$ of the recovered label from the skin, and its apparent half-life was 17.8 hr. Pretreatment of adult skin with TPA (10 μg/wk for 4 wk) before treatment with ^{3}H-TPA increased the clearance rate of TPA from the skin. Skin from newborn BALB/c mice was capable of converting TPA into monoesters and phorbol, but the clearance rate in the adult was about 12 times more rapid than that in the newborn. Epidermal homogenates converted TPA 12-O-tetradecanoylphorbol (TP), phorbol-13-acetate, and phorbol. Hepatic homogenates converted TPA to monoesters and phorbol at rates 14 to 15 times faster than those of the epidermal homogenates. Attempts to isolate any previously undescribed TPA metabolites by liver homogenates were unsuccessful, and mixed-function oxidation did not contribute to TPA metabolism. The conversion of TPA to monoesters and phorbol appeared to be related to esterase activity, since α-naphthol acetate inhibited TPA conversion to TP. (36 refs)

78-3232 **Progesterone Receptor Levels in Estrogen-induced Renal Carcinomas after Serial Passage Beneath the Renal Capsule of Syrian Hamsters.** (Eng) Lin, Y. C. (Dept. Biological Chemistry, Harvard Medical Sch., Boston, MA, 02115); Talley, D. J.; Villee, C. A. *Cancer Res* 38(5): 1286-1290; 1978.

Diethylstilbestrol-induced renal tumors in castrated male Syrian hamsters were serially transplanted and examined to determine whether progesterone receptor concentrations change as a function of serial passage. Fragments of primary tumor transplanted subpannicularly in estrogen-treated hamsters increased $< 10\%$ in mass during a 2-mo period; however, transplantation of primary tumor tissue beneath the renal capsule resulted in a 20- to 30-fold increase in tumor mass after 2 mo. There was no statistically significant difference in tumor concentration of progesterone receptor after the first or second serial passage relative to the concentration found in primary tumor tissue. Although the concentration of progesterone receptor was not significantly decreased after the second serial passage, there was a slower growth rate of tumors during this period. In addition to the reduced growth rate, a lower concentration of progesterone receptor was found in untransformed kidney areas of hosts bearing second-serial-passage tumors relative to those with first-passage or primary tumors. The serum concentration of diethylstilbestrol in tumor-bearing hosts was 2 to 4 x 10^{-8} M, and apparently it was not a factor in the change in growth rate of the tumors. It is suggested that the slower growth rate of the tumors after the second serial passage is related to an invasive property or surface change in the tumor cells rather than to significant changes in hormone receptor site concentrations within the cells. 78-3236 **Studies of Estrogen Induced Renal Tumours in Male Syrian Hamsters. I. Cytochemical Studies of Lysosomal Enzymes Acid Phosphatase and β-Glucuronidase.** (Eng) Ismail, A. A. (Tumour Cell Biology Dept., Medical Res. Inst., Alexandria Univ., Alexandria, Egypt); Hamilton, J. M.; Amin, A. M. *Acta Histochem (Jena)* 61(2): 287-295; 1978.

Cytoenzymological changes occurring during diethylstilbestrol (DES)-induced renal tumorigenesis were determined in male Syrian hamsters. The hamsters were inoculated sc with 0.6 mg DES 3x/wk. After 175 days, slightly elevated, white, solid subcapsular nodes were seen. After 225 days, tumor formation was obvious. In normal kidney cells, azo-coupling techniques showed that acid phosphatase (AP) and β-glucuronidase (GU) granules were distributed throughout the cytoplasm, but not in the nuclei. The degree of staining was moderate. During DES treatment, the distribution pattern of the two enzymes did not change. However, there was a gradual increase in AP and GU activity starting at 12 wk (21.6 mg DES) to a max at 30 wk (56 mg DES), when tumors were observed. The staining was intense. The increased enzyme activity could be due to a higher rate of lysosomal enzyme synthesis in the tumor cells or to invasion of tumor tissue by hydrolase-rich macrophages. (15 refs)

78-3237 **Developmental Abnormalities in the Mouse Genital System Associated with Prenatal Exposure to Diethylstilbestrol (Meeting Abstract).** (Eng) McLachlan, J. A. (Natl. Inst. Environmental Health Sciences, Res. Triangle Park, NC, 27709). *In Vitro* 14(4): 333; 1978. (no refs)

78-3238 **Metabolism of Diethylstilbestrol in the C3H Mouse: Chromatographic Systems for the Quantitative Analysis of DES Metabolic Products.** (Eng) Helton, E. D. (Food and Drug Admin., Natl. Center Toxicological Res., Jefferson, AR); Gough, B. J.; King, J. W.; Thenot, J. P.; Horning, E. C. *Steroids* 31(4): 471-484; 1978.

Chromatographic systems were used to study the metabolism of diethylstilbestrol (DES) in female C3H mice. Preliminary excretion studies with po monoethyl-1-^{3}H-DES indicated that excretion via the feces was the principal mode of DES elimination. Metabolic studies with po ^{3}H-DES and/or ^{14}C-DES were performed in mice with a high (+) or a low (-) titer of mouse mammary tumor virus (MMTV). Extraction and partitioning of the fecal radioactivity indicated that 77%-86% was benzene-soluble, the remainder water-soluble. The principal product in the organic phase following purification was DES. Analysis of the aqueous phase following 5β-glucuronidase digestion demonstrated that the principal aglycone was chromatographically identical to DES. The urinary conjugates were resolved into six fractions. The four major fractions were 80% hydrolyzable with β-glucuronidase. Two of these fractions had *trans*-DES as the principal aglycone, but the other two had a major peak similar to, but not chromatographically coincident with *cis*-DES. In additional experiments, MMTV + and MMTV- mice were dosed with ^{3}H-DES, the urine and feces were collected for 24 hr, they were then dosed with ^{14}C-DES, and again urine and feces were collected for 24 hr. Two MMTV+ mice were also previously fed a diet containing 1,000 ppb DES for 120 days. The labeled excretion products were combined and analyzed simultaneously. There were no significant differences in metabolism due to the modes of radioactive labeling, MMTV titer, or prior feeding of DES. (32 refs)

78-3239 **Stochastic Late Effects after Partial Body Irradiation in Diagnostic Radiology: Evaluation of Approximate Data.** (Eng) Pauly, H. (Institut fur Radiologie der Universitat Erlangen-Nurnberg, Krankenhausstrasse 12, D-8520 Erlangen, W. Germany). *Radiat Environ Biophys* 15(1): 21-33; 1978.

A method is described for estimating the risk of a patient developing cancer after partial-body, diagnostic x-ray exposure. The cumulative possibility, *p*, of a radiation-induced neoplasm is obtained from the equation $p = Gt\ Es$, where *Es* is the energy imparted to the soft tissues of the trunk and head. *Gt* is the mean integral incidence function for the trunk and head, reflecting the cancer inducibility of organs and tissues at these sites. The value of *Gt* [0.3 kilojoule^{-1} (kJ^{-1})] was obtained from mortality risk factors adopted by the International Commission on Radiological Protection. The *Es* imparted to the body in typical radiographic procedures ranges from 1 to 30 mJ, but it can reach 1 J in an extensive fluoroscopic examination of the gastrointestinal tract. The corresponding values for *p* are 10^{-6} to 10^{-5} in typical examinations, 10^{-4} in extensive examinations. (14 refs)

78-3240 **Preliminary Report on Radiation and Heart Disease.** (Eng) Bross, I. D. (Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263); Ball, M.; Rzepka, T.; Laws, R. E. *J Med* 9(1): 3-15; 1978.

The hypothesis that low levels of diagnostic radiation can produce both leukemia and heart disease in men was tested using data from the Tri-State Survey (New York, Maryland, and Minnesota) and a mathematical model. The radiation range considered was within a factor of 10 of 5 rads (0.5-50 rads). The results indicate that even at the lowest levels, an estimated 5% of exposed men will suffer DNA damage that will result in heart disease or leukemia. For the minority of individuals affected by the radiation, there is a tenfold increase in the risk of leukemia and a threefold increase in the risk of heart disease. (11 refs)

78-3241 **Hashimoto's Thyroiditis: The Commonest Radiation-induced Thyroid Disease (Meeting Abstract).** (Eng) Okerlund, M. D. (Nuclear Medicine Section, Univ. California Medical Center, San Francisco, CA); Beckmann, A.; Caro, M.; Sommers, J.; Kaufman, L.; Galante, M.; Hunt, T. *Clin Res* 26(2): 107A; 1978. (no refs)

78-3242 **Radiation-induced Thyroid Tumors in Infant Rats.** (Eng) Christov, K. (Inst. Oncology, Acad. Medicine, Sofia-56, Darvenitza, Plovdivsko pole 6, Bulgaria). *Radiat Res* 73(2): 330-339; 1978.

The susceptibility of the thyroid gland in infant rats to the carcinogenic effect of x-rays was examined with doses similar to those used to treat the hyperplastic thymus in human infants. Irradiation of 10-day-old Wistar rats with 300 rads of x-rays led to the development of thyroid tumors in 40% of the animals 15 mo later, whereas the same dose caused tumor growth in 15% of adult animals (60 days old). The latent period was also shorter in animals irradiated as infants. A subsequent treatment of irradiated animals with methylthiouracil significantly increased the number of thyroid adenomas and carcinomas and shortened the latent period in both infant and adult rats. The thyroid tumors examined were predominantly of a follicular type. Papillary and medullary tumor variants were observed in a few animals only. The results indicate that the thyroid gland of suckling animals is more susceptible to the tumorigenic stimulus of x-radiation than that of adult animals. (24 refs)

78-3243 **Carcinogenic Effect of Isolated and Combined Chronic External (Gamma) and Internal (^{131}I) Radiation on Rats.** (Rus) Burykina, L. N. (Inst. Occupational Hygiene and Vocational Diseases, Moscow, USSR); Vasil'eva, L. A.; Likhachev, Iu. P.; Ponomareva, V. L.; Veselovskaia, K. A. *Med Radiol (Mosk)* (4): 35-40; 1978.

The long-term effects of chronic exposure to ^{131}I combined with prolonged whole body radiation were studied in random-bred albino rats. The animals were divided into five groups: Groups 1 and 2 received ^{131}I (1-2 x 10^{-4} and 0.25 x 10^{-4} μCi/g/day, respectively, daily, for 6 mo; total absorbed dose, 1,900-3,000 and 700 rads, respectively); Group 3 received whole-body ^{137}Cs γ radiation (0.4-0.8 R/day, 5x/wk, total dose, 50-100 rads); Group 4 received ^{131}I + γ radiation (total absorbed dose 1,600-2,600 rads); Group 5 served as the control group. The av duration of survival in the groups was 606, 623, 617, 611, and 645 days, respectively. Tumors were observed in 67.2% of rats in Group 1 (44.4% had thyroid tumors), 57.5% in Group 2 (14.8%), 54.2% in Group 3 (6.8%), 66.0% in Group 4 (40.9%), and 33.8% in Group 5 (7.9%). The structural changes in the thyroid tissue were more pronounced in Group 4 rats (compared with rats in Groups 1 and 2). (8 refs)

78-3244 **Long-Term Results of Administration of Uranium to Rats.** (Rus) Filippova, L. G. (No affiliation given); Nifatov, A. P.; Liubchinskii, E. R. *Radiobiologiia* 18(3): 400-405; 1978.

The long-term results of intratracheal administration of various doses of uranium (U) were studied in Wistar rats. Animals received a single dose of the nitrate salt of U(IV) or U(VI). Exposure to 19.5 mg/kg U(VI) resulted in 100% mortality within 30 min; exposure to 9.76 mg/kg and 5.82 mg/kg U(VI) resulted in 100% and 42.6% mortality, respectively, within 2 wk. Administration of 18.7 mg/kg U(IV) resulted in 31% mortality within the first wk of exposure (the life-span of the survivors was decreased by approx 100 days). From 72.7% to 79.3% of the animals exposed to U(IV) and U(VI) at 5.27-5.82 mg/kg died of nephrosclerosis. Osteogenic sarcomas were detected in 2.9% and 5.5% of the rats exposed to 1.57 and 5.82 mg/kg U(VI) and in 2.0% and 4.5% of the rats exposed to 2.85 and 5.27 mg/kg U(VI), respectively. (9 refs)

78-3245 **The Effect of Chronic Exposure to ^{238}Pu(IV) Citrate on the Embryonic Development of Carp and Fathead Minnow Eggs.** (Eng) Till, J. E. (Environmental Sciences Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830). *Health Phys* 34(4): 333-343; 1978.

The effects of plutonium (Pu) on developing fish eggs were studied. A quantitative analysis of ^{238}Pu(IV) citrate uptake by carp eggs indicated that Pu accumulated in the eggs and reached a concentration factor of approx 4 at hatching (72 hr after exposure began). Autoradiographs revealed that although some Pu was concentrated on the egg chorion, the Pu that penetrated the chorion was uniformly distributed throughout the perivitelline fluid, embryo, and yolk sac. Using the uptake data for carp eggs, dose conversion factors were calculated for both carp eggs and fathead minnow eggs exposed to ^{238}Pu during embryological development. These values were 2,100 and 7,500 rads/μCi/ml for carp and fathead minnows, respectively. Experiments were conducted in which both carp and fathead minnow eggs were exposed to Pu in soln during embryogenesis; the percentage of eggs hatching, the number of abnormal larvae produced, and the survival of larvae were the indicators of radiation toxicity. Concentrations >1 μCi/ml were required to prevent both species of eggs from hatching. It is concluded that fish eggs developing in natural aquatic ecosystems contaminated with Pu probably do not receive a significant dose from the Pu alpha radioactivity. Future analysis of fecundity and the production of abnormalities in the offspring of larvae exposed during embryological development would provide an additional degree of sensitivity to the toxicity test system used here. (19 refs)

78-3246 **Distribution and Kinetics of Metabolism of ^{238}Pu after Intratracheal Administration to Rats.** (Rus) Nisimov, P. G. (No affiliation given). *Radiobiologiia* 18(3): 406-411; 1978.

The distribution and kinetics of metabolism of intratracheally administered ^{238}Pu were studied in random-bred rats. The animals received a soln of ^{238}Pu nitrate (2.5 μCi/kg), and the animals were sacrificed 0.5 hr to 226 days later. Tissue residues of the radionuclide were determined histoautoradiographically. Almost 24% of the radioactivity was eliminated from the lungs within 30 min of administration, 43.7% over 42 hr, 30.4% over 10 days, and 1.84% over 226 days. The max concentration of ^{238}Pu in the liver (8.26%) was detected 24 hr after administration (48.45% of liver radioactivity was eliminated within 7 days, and 51.55% was eliminated within 30 days). The accumulation of radioactivity in the bone tissue increased gradually from 4.11% on day 1 after administration to 30.31% on day 3, 49.31% on day 16, and 53.39% on day 32. (5 refs)

78-3247 **Distribution of Tritium in the Different Organs of Calves and Pigs After Ingestion of Various Tritiated Feeds.** (Eng) Kirchmann, R. (Dept. Radiobiology, C.E.N./S.C.K., B-2400 Mol, Belgium); Charles, P.; van Bruwaene, R.; Remy, J.; Koch, G.; van den Hoek, J. *Curr Top Radiat Res* 12(1): 291-312; 1977.

The distribution of tritium (^{3}H) administered as tritiated water (HTO) or incorporated in feed was studied in male calves and pigs. Three calves received fresh milk supplemented with 50 μCi/ml HTO (total ^{3}H activity ingested over a 28-day period: 25.6-40.4 μCi/animal). Two other calves received 125 g ^{3}H-powdered milk (total ingested activity: 482 μCi/calf). Pigs in groups of two or three animals were treated as follows: (1) a single ip injection of 39.3 μCi HTO; (2) 28.4 μCi/day HTO (total ingested activity: 568 and 766.8 μCi/animal); (3) ^{3}H-potatoes (total ingested activity: 21-48.1 μCi/animal); and (4) ^{3}H-powdered milk (total ingested activity: 60.6-154 μCi/animal). After the animals were slaughtered, ^{3}H concentrations were determined in tissue water and organic matter. Ingestion of ^{3}H powdered milk, compared with HTO, increased the total incorporation in organic matter by a factor of 5.6 in the pigs and a factor of 15 in the calves. In pigs fed the ^{3}H potatoes, there was a 15.6-fold increase in incorporation. For both species, the specific activity in the tissue water f the organs was a little lower than that of ingested HTO. 'he activity was very low after the ingestion of ^{3}H-milk, and here were no species differences. Radioactivity was found in ll the nucleic acids, lipids, and proteins isolated from pig ver and spleen. However, there was no evidence that ^{3}H was ctually incorporated into the DNA molecules of the liver an organ consisting of nondividing cells) or the spleen (an rgan containing actively dividing cells). (10 refs)

8-3248 **Retention and Distribution of ^{241}AmIII in Neonatal Beagles.** (Eng) Stevens, W. (Radiobiology Div., Dept. Anatomy, Univ. Utah, Salt Lake City, UT, 4132); Atherton, D. R.; Bates, D.; Lloyd, R. D.; Buster, D. .; Bruenger, F. W. *Health Phys* 33(6): 553-559; 1977.

The distribution of americium in beagles was studied during heir first week of life. Seven litter mates (4 males, 3 female 250-280 g) were inoculated iv with 3.0 μCi ^{241}AmIII/kg when 1 day old and killed 1, 3, or 5 days later. Cumulative excretion during the time observed was 6.7% of the dose, 5.5% of which occurred during the first day. Mean recovery of the injected Am was 96%. The deposition of Am in the skeleton and soft tissues was compared to data obtained from three beagles inoculated with an equivalent dose of Am when 18 mo old and sacrificed 1, 7, and 8 days later. Skeletal retention was 76% of the injected dose at 1 day and 84% at 5 days in the neonates. The skeletons of the 18-mo-old beagles contained 29% of the dose at 1 wk. The Am content of the bones in the neonatal skull was three times that seen in dogs inoculated as young adults. Initial liver deposition of Am in neonates was 7%, compared to 50% in young adult dogs. The subcellular distribution of Am in liver also differed in the two groups: in neonates, a greater fraction of the nuclide was associated with soluble cytosol proteins, and the Am content of mitochondria and lysosomes increased at a much slower rate than that observed in mature animals. It is speculated that the relatively low retention in the soft tissue organs of the neonate should make them less susceptible to radiation damage. However, the mineralized tissue, which retains 80% of the injected dose, is in a state of rapid growth and reorganization, and an increased incidence of early bone tumors may occur. (13 refs)

78-3249 **Postprandial Changes in the Exhalation Rate of Radon Produced In Vivo.** (Eng) Rundo, J. (Center for Human Radiobiology, Argonne Natl. Lab., Argonne, IL, 60439); Markun, F.; Sha, J. Y. *Science* 199(4334): 1211-1212; 1978.

Changes in the rate of exhalation of radon following a meal were investigated in several radium dial painters first exposed to radium between 1916 and 1925 and in one man involved in a radium spill in 1952. There was a radon exhalation rate at about 0.5 hr after a meal, followed by a decrease to normal values by 1.5-2 hr. There was also a strong correlation between the exhalation rate of radon and the pulse rate. This suggests rate of range in radon exhalation observed postprandially is related to the change in blood flow associated with the digestive processes. This could represent the flushing of a radon reservoir in the viscera. (7 refs)

78-3250 **Natural and Manmade Radiation Exposure.** (Ger) Mehl, J. (Bundesministerium des Innern, Postfach, D-5300 Bonn 7, W. Germany). *Kertechnik* 20(5): 221-228; 1978.

Annual dose-equivalent values for various organs and tissues and annual effective whole-body dose-equivalent values resulting from exposure to natural and manmade radiation were assessed. The prospective incidence rates of radiation-induced diseases, including cancer and leukemia, in West Germany were calculated by assuming a linear dose-effect relationship and by using risk factors published by the International Commission on Radiological Protection. The incidence rates of radiation-induced cancers and leukemias are compared with the spontaneous incidence rates for 1974. The data should be useful in the development of a program to reduce the deleterious effects of ionizing radiation. (21 refs)

78-3251 **Sister-Chromatid Exchange Induced by X-Ray of Human Lymphocytes and the Effect of L-Cysteine.** (Eng) Abramovsky, I. (Div. Medical Genetics, Dept. Pediatrics, Mount Sinai Sch. Medicine, City Univ. New York, Fifth Ave. and 100th St., New York, NY, 10029); Vorsanger, G.; Hirschhorn, K. *Mutat Res* 50(1): 93-100; 1978.

The characteristics of sister-chromatid exchanges (SCE's) detectable in normal human lymphocytes exposed to different dosages of x-radiation were studied. All irradiations (25 to 200 rads) were performed on cells that had completed at least one round of replication in 5-bromo deoxyuridine (BUdR). A significant dose-dependent increase in SCE's per cell occurred when the lymphocytes were irradiated in the G_1 phase of their second mitotic division. A slight increase was noted after irradiation of lymphocytes in the G_2 phase. Cellular viability was reduced markedly in the G_1 lymphocytes at 200 rads and in the G_2 lymphocytes at 50-100 rads. The increase in SCE frequency was accompanied by an increase in chromosome aberrations: terminal deletions, interstitial deletions, and chromosome exchange figures in G_1 cells; chromatid gaps, breaks, and exchanges in G_2 cells. The antimutagen L-cysteine decreased the frequency of SCE's in irradiated G_1 cells, although the frequency was still significantly higher than in nonirradiated cells. L-cysteine increased cell viability, especially after radiation doses of 100 rads or more. However, the addition of L-cysteine to lymphocytes that had been exposed to x-radiation did not reduce SCE frequency or cell death significantly. An analysis of SCE's in human cells may provide a sensitive and reliable method for screening potential chromosome mutagens. (23 refs)

78-3252 **Spontaneous and Radiation-induced Oncogenesis in Hamsters.** (Eng) Trentin, J. J. (Div. Experimental Biology, Baylor Coll. Medicine, Houston, TX, 77030). *Fed Proc* 37(7): 2084-2086; 1978.

An attempt was made to increase the incidence of lymphomas in weanling Syrian hamsters by fractionated radiation. The animals received 240 R of whole-body x-radiation once a week for 4 wk. Of 22 hamsters surviving >60 days, only 1 developed a lymphoma weekly. Doses of 20, 40, 80 or 150 R were then given for 10, 20, or 30 wk. Of 185 animals that survived the treatment, 13 had tumors, mostly of the liver and spleen, at autopsy. These tumors were diagnosed as reticulum cell sarcomas, small cell sarcomas, or undifferentiated tumors of the liver and spleen. The highest tumor incidence was only 12%-13% in the four highest total exposure groups (1,500, 1,600, 2,400, and 3,000 R). These findings indicate that, compared with the mouse, the hamster is remarkably more resistant to irradiation lymphomagenesis. The nature of this resistance is not known. (16 refs)

78-3253 **Comparison of Survival and Unscheduled DNA Synthesis Between an Insect and a Mammalian Cell Line Following X-Ray Treatments.** (Eng) Koval, T. M. (Cancer Res. Unit, Clinical Radiation Therapy Res. Center, Allegheny General Hosp., Pittsburgh, PA, 15212); Myser, W. C.; Hart, R. W.; Hink, W. F. *Mutat Res* 49(3): 431-435; 1978.

Survival and unscheduled DNA synthesis following x-irradiation were compared in insect cells from the *Trichoplusia ni* (TN-368) cabbage looper cell line and V-79 Chinese hamster cells. The TN-368 cells were x-irradiated with 0.5 to 10 kR, and the V-79 cells with 0.05-1 kR, and incubated for 7 days, and plating efficiencies were counted. The TN-368 cells were >30 times more resistant to x-rays than the V-79 cells. In the unscheduled DNA synthesis study, the TN-368 cells incorporated >10 times more ^{3}H thymidine via unscheduled DNA synthesis than the V-79 cells after each of the three x-ray exposures (0.5, 1.0, and 1.5 kR) investigated. Both the rate and extent of unscheduled DNA synthesis were much greater in the TN-368 cells. The extent of unscheduled DNA synthesis is correlated with the excision repair of DNA base damage, since single-strand break repair was essentially complete by 30 min and unscheduled DNA synthesis continued for at least 4 hr. The high yield of unscheduled DNA synthesis in TN-368 cells after x-irradiation is due to their havi a larger av size for x-ray-repaired regions or a greater numb of repaired regions per unit length of DNA. (10 refs)

78-3254 **Mammary and Other Tumors as a Response t Radiation and Multiple Stresses.** (Eng) Warre S. (194 Pilgrim Road, Boston, MA, 02215); Brown, C. *Arch Pathol Lab Med* 102(5): 224-226; 1978.

Tumor incidence was investigated in female NEDH rats tha were parabiosed at about 35 days of age. Torsion between th partners was prevented by approximating the adjacent scapulae of the partners using a suture of either braided stainles steel or tantalum. Subsequently, one partner received 1,00 R whole-body 250-kilovolt peak x-radiation while the othe partner was shielded by lead. Benign mammary tumors developed in 8.6% of the control pairs, 12.7% of the shielde partners, and 19.7% of the irradiated rats. Mammary cancer developed in 5% of the control pairs, 14.2% of the shielde partners, and 11.9% of the irradiated rats. When a hormona imbalance was imposed by unilateral nephrectomy i each rat (which increased prolactin levels), th mammary cancer rate was 50% in the shielded partn and 10% in the irradiated rats. Mesenchymal sarcom developed at the anastomosis in parabiont rats. Th incidence rate in single controls was 3.1%, in par biont control pairs 12.5%, in pairs with one partn irradiated 16.6%, and in pairs with both irradiate 23.1%. About 33% of these sarcomas occurred at the junction of the scapulae, where the metallic suture was presen as a foreign body. Tumor incidence elsewhere in irradiate partners was increased threefold over controls. It is suggeste that radiation is the dominant factor in both mammary an anastomotic tumors. (8 refs)

78-3255 **Effects of Radiation Type and Dose and th Role of Glucocorticoids, Gonadectomy, an Thyroidectomy in Mammary Tumor Induction in Mammotropin-secreting Pituitary Tumor-grafted Rats.** (Eng) Clifton, K. H. (Radiobiology Labs., 420 N. Charter St., Madison WI, 53706); Crowley, J. J. *Cancer Res* 38(6): 1507-1513 1978.

The effects of 11-100 rads' neutron or 50-500 rads' γ-ra whole-body radiation, glucocorticoids, gonadectomy, an thyroidectomy on mammary tumor induction in mammotropin-secreting pituitary tumor (MtT)-grafted Fischer an W/Fu rats were determined. These studies yielded the following results: (1) neutrons were significantly more efficient tha γ-rays in the induction of mammary carcinomas; (2 adrenalectomy with mineralocorticoid replacement potentiated mammary carcinoma induction in irradiated MtT-grafted rats; (3) potentiation of carcinoma induction b adrenalectomy was reversed by glucocorticoid treatment; an

4) gonadectomy and thyroidectomy of irradiated MtT-graft-d Fischer rats did not potentiate mammary carcinoma inluction as did glucocorticoid deficiency and, in combination vith the latter, they may reduce the adrenalectomy effect. tatistical analysis of the data by procedures that take into ccount time at risk as well as tumor frequency indicates that nultiple mammary tumors do not occur independently (ie, first mammary tumor significantly increases the probability f development of another tumor). The statistical procedure sed in this analysis is presented. (25 refs)

8-3256 **Leukemia Risk from Neutrons.** (Eng) Rossi, H. H. (Radiobiological Res. Lab., Dept. Radiology, Coll. Physicians and Surgeons, Columbia Univ., 630 W. 168th St., New York, NY, 10032); Mays, C. W. *Health Phys* 34(4): 353-360; 1978.

The leukemia incidence among atom bomb survivors was reevaluated in terms of absorbed dose to the marrow, and the results were used to estimate the risk from present permissible neutron doses. The predicted lifetime incidence of leukemia is 800 cases/1,000,000 persons exposed to a 1-rad dose to the marrow. For a 50-yr occupational exposure at the max permissible dose of 0.5 rad/yr to marrow and total body, the leukemia incidence will be 2%, a value that is five times higher than the naturally occurring lifetime incidence of 0.4% in the US. Because these risks are unacceptably high, current permissible neutron doses should be reduced by at least one order of magnitude. (15 refs)

78-3257 **The Effect of 8-Methoxypsoralen Plus UV-Light on the Frequency of Viral Transformation by Polyoma Virus In Vitro (Meeting Abstract).** (Eng) Morhenn, V. B. (Dept. Dermatology, Stanford Univ. Sch. Medicine, Stanford, CA); Kaye, J. A. *Clin Res* 26(3): 573A; 1978. (no refs)

78-3258 **Ultraviolet-Light-induced Unscheduled DNA Synthesis by Resting and Growing Mouse Oocytes.** (Eng) Pedersen, R. A. (Lab. Radiobiology, Univ. California, San Francisco, CA, 94143); Mangia, F. *Mutat Res* 49(3): 425-429; 1978.

Resting (from 2- to 3-day old mice) and growing (from 12- to 13-day old mice) mouse oocytes were exposed to UV light (0, 15, 30, or 60 joules/m^2), cultured in medium containing ^{3}H-thymidine, and examined for unscheduled DNA synthesis by autoradiography as a measure of DNA excision repair. Both resting and growing oocytes incorporated ^{3}H-thymidine into their nuclei in significantly greater amounts than control (unirradiated) oocytes. Growing oocytes, however, incorporated about six times more ^{3}H-thymidine than resting oocytes. There are several possible explanations for this difference: the rates of thymidine uptake and its endogenous pool size may differ between stages; the actual amount of damage to the DNA of resting and growing oocytes may be different; and growing oocytes may actually have higher activities of excision-repair enzymes. It is concluded that both resting and growing oocytes are capable of unscheduled DNA synthesis after UV irradiation. (19 refs)

78-3259 **Neoplastic Transformation Induced by a Direct Perturbation of DNA.** (Eng) Barrett, J. C. (Natl. Inst. Environmental Health Sciences, NIH, P.O. Box 12233, Research Triangle Park, NC, 27709); Tsutsui, T.; Ts'o, P. O. *Nature* 274(5668): 229-232; 1978.

The effects of 5-bromodeoxyuridine (BUdR) and/or near-UV radiation on Syrian hamster embryo (SHE) cells were investigated. BUdR alone (10^{-6} M for 24 hr) was cytotoxic to early-passage SHE cells, and exogenous deoxycytidine reduced this effect. Irradiation with near-UV light (6 fluorescent bulbs at a distance of 7.5 cm; approx 330 ergs/mm^2/sec) for 1-5 min after BUdR treatment significantly enhanced the lethality of the latter and resulted in single-strand breaks in cellular DNA. BUdR followed by near UV irradiation, but neither agent alone, caused somatic mutations in the hypoxanthine phosphoribosyltransferase and (Na^+, K^+) ATPase loci. BUdR (2.5 x 10^{-6} M for 24 hr) plus irradiation for 1 or 3 min also caused morphological transformation and neoplastic transformation in SHE cells. Cells from transformed cultures exhibited colony formation in soft agar and formed tumors after injection into newborn hamsters. Cytotoxicity, single-strand breakage, mutation frequency, and morphological transformation increased with increasing dosage of irradiation, and cytotoxicity and morphological transformation increased with BUdR dose. The data suggest that a direct perturbation of cellular DNA is sufficient to initiate neoplastic transformation. (22 refs)

78-3260 **Effects of Ultraviolet Light on Nude Mice. Cutaneous Carcinogenesis and Possible Leukemogenesis.** (Eng) Eaton, G. J. (Inst. Cancer Res., Fox Chase Cancer Center, 7701 Burholme Ave., Philadelphia, PA, 19111); Custer, R. P.; Crane, A. R. *Cancer* 42(1): 182-188; 1978.

The effects of UV irradiation (14.8 millijoules/hr for 2 hr, 5 days/wk) on nude mice (nu/nu) of two different genetic backgrounds (BALB/c and C57BL/6), their congenic partners (+/+), and hairless (hr/hr) mice were studied. All nu/nu mice died within 117 days without developing cancers, although three did develop papillomas. Multiple squamous cell carcinomas were induced after an av of 176 (BALB/c) or 194 (C57BL/6) exposures in all seven nu/nu mice that had been reconstituted with syngeneic spleen cells prior to treatment. In two C57BL/6 mice, there were metastases to the lungs and lymph nodes. No tumors appeared in the congenic BALB/c mice after 317 exposures, and only one tumor arose in the congenic C57BL/6 mice after 244 exposures. In contrast, multiple tumors developed in all 24 hr/hr mice after 61-136 exposures, and one tumor metastasized to the lungs. All tumors were epidermal in origin, and they varied in degree of differentiation from simple hyperkeratosing papillomas to highly anaplastic types with abundant mitotic activity. Striking granulocytic proliferation was provoked in one hr/hr and in five reconstituted nu/nu mice; two of the latter appeared to have true granulocytic leukemia. The results demonstrate the susceptibility of athymic nude mice to the cutaneous carcinogenic activity of UV light, provided their life-spans are extended to permit prolongation of the irradiation. (9 refs)

78-3261 **Ultraviolet Exposure and Skin Cancer Response.** (Eng) Green, A. E. (ICAAS, Space Sciences Res. Bldg., Univ. Florida, Gainesville, FL, 32611). *Am J Epidemiol* 107(4): 277-280; 1978.

The response of human skin to exposure to UV light is considered in terms of the applicability of reciprocity to the problem. Reciprocity holds if the cumulative risk S to a homogeneous population group of age A is a function of the cumulative exposure E = DA (D is the UV dose/yr). If reciprocity were known to work even approximately, dose dependence could be inferred from age dependence. The reciprocity implications for UV exposure leading to skin cancer were calculated mathematically. The results suggest that reciprocity fails for nonmelanoma skin cancer but that it may hold for melanoma skin cancer. (16 refs)

78-3262 **Fluorescent Light-induced Chromosome Damage and Its Prevention in Mouse Cells in Culture.** (Eng) Parshad, R. (Dept. Pathology, Howard Univ. Coll. Medicine, Washington, DC, 20059); Sanford, K. K.; Jones, G. M.; Tarone, R. E. *Proc Natl Acad Sci USA* 75(4): 1830-1833; 1978.

A 20-hr exposure to fluorescent light produced chromatid breaks in adult mouse C57BL/6N lung cells grown in Dulbecco-Vogt medium supplemented with fetal bovine serum. The light-induced damage was enhanced slightly by increasing the oxygen concentration in the gas phase of the culture. The effective wavelength(s) of light was in the visible range between 400 and 450 nanometers (nm), and it was probably the mercury emission peak at 405 or 436 nm. Addition of catalase or glutathione with ascorbic acid to the culture medium reduced the number of chromatid breaks to a level not significantly different from that in the shielded cultures Thus, the production of H_2O_2 in the culture medium or in the cell was apparently responsible for the chromatid breaks Most chromosome abnormalities observed in long-term cultures of mouse cells may result from exposure of cells o medium to fluorescent room light in the presence of atmospheric oxygen. These genetic abnormalities can be minimized by shielding cells and medium from light, lowering the oxygen partial pressure of the medium, and including reducing agents such as glutathione and ascorbic acid in the medium (21 refs)

78-3263 **Photoaugmentation: A Photobiological Phenomenon.** (Ger) Spiegel, H. (Dermatologische Klinik und Poliklinik, Universitat Munchen, Frauenlobstrasse 9-11, D-8000 Munich 2, W. Germany); Plewig, G. Hofmann, C.; Braun-Falco, O. *Arch Dermatol Res* 261(2) 189-200; 1978.

The phenomenon of photoaugmentation was investigated in 37 subjects (aged 15-78 yr) of both sexes. UVA, UVB, UVC were applied with a high-intensity grating monochromator Photoaugmentation could be induced following UVA plus UVB or up to 3 hr later, but not after 24 hr UVA [351-389 nanometers (nm)] at 15 joules (J)/cm^2 and UVB (290-310 nm) at 13 mJ/cm^2 resulted in one-half the minima erythema dose. The reversed application of UVB plu UVA also led to photoaugmentation. With UVA plu UVC, photoaugmentation could not be elicited i every patient. Photoaugmentation was also demonstrated in albino rabbits using a new light apparatu with a liquid-filled light-conducting core. Photoaugmentation seems to be an important biological phenomenon in association with sunburn, pigmentation, phototoxicity, phototherapy, photochemotherapy, and UV light-induced cutaneous premalignancies and malignancies. (22 refs)

78-3264 **Solar Radiation: A Possible Etiological Factor in Malignant Melanoma in Israel. A Retrospective Study (1960-1972).** (Eng) Anaise, D. (Surgical Service Office, Veterans Admin. Hosp., Northport, NY, 11568); Steinitz, R.; Ben Hur, N. *Cancer* 42(1): 299-304; 1978.

The role of excessive sunlight exposure on the incidence of malignant melanoma was studied based on 966 malignant melanoma cases reported to the Israeli cancer registry between 1960 and 1972. The annual incidence rose from 20/million in 1960 to 40/million in 1970. The age-adjusted incidence rate was 34/million among Jews from Europe and America, 2.7/million among Jews from Africa and 4.1/million among Jews from Asia. The incidence among European-born Jews who had been expose o the Isreali climate for 20-30 yr prior to diagnosis as 58/million, compared with only 17/million among uropean-born Jews who had immigrated to Israel nly 2-5 yr before diagnosis. The disease tended to anifest itself on the lower extremities in women (55% n those aged 50-79 yr and 41% in those aged 0-19 yr) and n the trunk in men (30.7%). The preponderance of the disease on the lower extremities of women was higher in those vho had been in Israel for 20-30 yr (61%) than in those who ad been in the country only 2-5 yr (49%). The age-adjusted ate was 20/million for Jerusalem compared with 35/million nd 32/million for Haifa and Tel Aviv, respectively, and it vas 54/million among Kibbutz dwellers compared with 17/million among city dwellers. It is suggested that the dark kin of the non-Caucasian races protects them against the evelopment of malignant melanoma. (13 refs)

78-3265 **Effect of Ultrasonic Irradiation on Mammalian Cells and Chromosomes in Vitro.** (Eng) Rosebo-ro, J. A. (Jet Propulsion Lab., California Inst. Technology, Pasadena, CA); Buchanan, P.; Norman, A.; Stern, R. *Phys Med Biol* 23(2): 324-331; 1978.

The effect of ultrasound on human peripheral blood lymphocytes, RBC's, and HeLa cells was examined in vitro at an ultrasonic frequency of 65 kilohertz. The whole blood and HeLa cell suspensions were exposed to continuous and pulsed ultrasonic power levels of 0.12-2.24 watts (W) for 1 min. Irradiation was carried out with the whole blood or HeLa cell suspensions coupled directly to a cylindrical transducer; heating of the cell suspensions above 41 C was avoided. Irradiated and unirradiated peripheral blood lymphocyte chromosome cultures were prepared and scored for selected numerical and morphological aberrations. There was no significant difference in the frequency of chromosomal aberrations between irradiated and unirradiated cells. Cell survival decreased with time after ultrasonic irradiation. The surviving fraction of lymphocytes was an exponential function of the ultrasonic energy to which the cells were exposed independently of the transducer power output over the full power range. RBC survival was independent of power only at levels > 0.7 W. Below this threshold, no destruction of RBC's was observed. The finding of an energy threshold for cell destruction has implications for the biological hazards of ultrasound, showing that peak power as well as av power is an important consideration. 78-3266 **Virus-Specific RNA Species Present in the Cytoplasm of Rous Sarcoma Virus-infected Chicken Cells.** (Eng) Brugge, J. S. (Dept. Pathology, Univ. Colorado Medical Center, Denver, CO, 80262); Purchio, A. F.; Erikson, R. L. *Virology* 83(1): 16-26; 1977.

The species of virus-specific cytoplasmic RNA found in wild-type (wt) and transformation-defective (td) Rous sarcoma virus (RSV)-infected chicken cells were studied. The RNA from each infected cell type was separated into polyadenylated and nonpolyadenylated RNA fractions, sedimented through sucrose gradients, and hybridized with a complementary DNA probe to identify the virus-specific RNA species. The ability of each class of RNA to serve as messenger RNA (mRNA) was ascertained by analysis of the RNA released from purified polyribosomes by puromycin. Two major species of virus-specific RNA were detected in the poly(A) fraction of wt and td RSV-infected chicken cells: one sedimenting at 35S and one sedimenting at 21S. Both species were released from polyribosomes with puromycin, the proportion of 35S RNA relative to 21S RNA being decreased in the puromycin-released RNA. A small amount of virus-specific RNA sedimenting slower than 14S was also detected in puromycin-treated and untreated RNA samples. The presence of two distinct virus-specific mRNA molecules suggests that the integrated provirus has internal sites for the initiation of transcription or that individual mRNA molecules are cleaved from 35S RNA. (32 refs)

78-3267 **Virus-specific RNA in Selected Cell Lines Derived from RSV-induced Tumour.** (Eng) Kisselyov, F. L. (Cancer Res. Center, Acad. Medical Sciences USSR, Moscow, USSR); Tatosian, A. G.; Svoboda, J. *Folia Biol (Praha)* 23(4): 225-234; 1977.

The presence of virus-specific RNA was studied in three Rous sarcoma virus (RSV)-transformed mammalian tumor cell lines. Line XC, derived from Wistar rats, was transformed by the Prague strain of RSV (PR-RSV) and is characterized by virogenic cells that contain a complete RSV genome. The other two tumor cell lines, RVP_3 (induced in mice by PR-RSV) and RVA_4 (induced in mice by the Schmidt-Ruppin strain of RSV), were nonvirogenic and did not contain any viral genome. Cellular RNA was hybridized to a PR-RSV ^3H-DNA probe synthesized by the endogenous RNA-directed DNA polymerase reaction. The RNA from RVA_4 cells did not hybridize with the ^3H-DNA probe of PR-RSV. The max level of hybridization was 28%-30% for RVP_3 and 10%-12% for XC cells. It was calculated that the virus-specific RNA amounts to 0.01% a 0.2% of the total high-mol-wt RNA in XC and RV cells, respectively. Sucrose gradient centrifugati indicated that the virus-specific RNA sedimented 20S-25S. RNA molecules that would have correspond to the complete virus genome (30S-40S) were nev seen. (27 refs.)

(Laboratoire Biologie Cellulaire et Moleculaire, Institut de Cancerolog et d'Immunogenetique, 14, avenue Paul-Vaillant-Couturie 94800 Villejuif, France); Mariage, R.; Goubin, G.; Rousse M.; Hillova, J.; Hill, M. *Bull Cancer (Paris)* 65(1): 40; 197 (no refs)

78-3269 **Identification of a Transformation-specific Pr tein Induced by a Rous Sarcoma Virus.** (Eng Jay, G. (Pediatric Oncology Branch, Lab. Molecular Biolog NCI, Bethesda, MD, 20014); Shiu, R. P.; Jay, F. T.; Levin A. S.; Pastan, I. *Cell* 13(3): 527-534; 1978.

A protein with an apparent mol wt of 56,000 daltons (56K and an isoelectric point of 6.3 was identified in extracts chick embryo fibroblasts transformed by a wild-type nonde fective Rous sarcoma virus (Schmidt-Ruppin strai SR-RSV) using antisera from rats bearing SR-RSV-induce tumors. This protein was not detected in cells infected b transformation-defective mutants with either a partial complete deletion of the *src* gene or in cells infected by nontransforming avian leukosis virus. The 56K protein wa synthesized at both the permissive and nonpermissive tem peratures in cells infected by either of two conditional-leth mutants (Ts68 and T5) that are temperature-sensitive in ce transformation. The 56K protein also accumulated to th same extent at both temperatures. However, the amount this protein that accumulated in cells infected by Ts68 or T relative to the structural polypeptides, differed significantl from that seen with the nondefective virus. The protein extremely unstable, with a half-life of 20 min, and it is n a precursor to any of the detectable virion polypeptides. Incu bation of the rat antiserum with purified, disrupted virus di not affect its immunoreactivity to this particular protein. is concluded that the 56K protein is a nonstructural protei specific to cells transformed by RSV. (37 refs)

-3270 **The Detection of Glycoproteins Immunological-**
ly Related to RSV gp85 in Uninfected Avian
ells and in Sera from Uninfected Birds. (Eng) Bosch, V.
mperial Cancer Res. Fund Labs., Lincoln's Inn Fields, Lon-
)n WC2A 3PX, England); Kurth, R.; Smart, J. E. *Virology*
)(1): 226-240; 1978.

ifferent antisera were used to examine the presence and
tent of relatedness of components that cross-react with the
ral glycoprotein (gp85) in avian cell extracts and in sera
om uninfected birds. Cell extracts from chick helper fac-
r-negative (chf-) fibroblasts contained components detected
/ anti-avian myeloblastosis virus (anti-AMV) gp85 and
ti-Prague B Rous sarcoma virus (RSV) sera, but not an-
-Prague C gp85 serum. Chf(+) chicken cell extracts con-
ined in addition an antigenic determinant, presumably viral
)85, recognized by anti-Prague C gp85 serum. The sera
om uninfected chickens may contain two components im-
unologically related to gp85. One component recognized
a radioimmunoprecipitation assay (RIA) employing an-
-AMV gp85 serum was present in high amounts in the sera
f chf(+) and chf(-) birds, but a second component detected
an RIA employing anti-Prague B RSV serum was present
nly in the sera of chf(+) birds. It is suggested that the com-
onents that immunologically cross-react with, but are not
lentical to, endogenous viral glycoprotein are products of
enes that are related to the *env* gene of Rous-associated virus
/pe 0 but are nonfunctional as viral glycoprotein. (38 refs)

8-3271 **The Generation of the Two Envelope Glyco-**
proteins of Rous Sarcoma Virus from a Com-
on Precursor Polypeptide. (Eng) Klemenz, R. (Swiss Inst.
xperimental Cancer Res., 1066 Epalinges, Switzerland);
iggelmann, H. *Virology* 85(1): 63-74; 1978.

he relationship of two envelope glycoproteins of Rous sar-
oma virus (gp85 and gp35) to each other and to a 92,000-dal-
on polypeptide from infected chicken embryo fibroblasts was
udied. The two envelope glycoproteins were purified from
H-arginine- and ^{35}S- and ^{3}H-methionine-labeled virus by aga-
ose gel filtration, and gp35 was further purified by sodium
odecyl sulfate gel electrophoresis. After removal of the ter-
inal sialic acid residues, the two glycoproteins were oxi-
ized and trypsinized, and the resulting peptides were sepa-
ated to a cation-exchange column. The results suggested that
p85 and gp35 do not share their major methionine- or argi-
ine-labeled peptides. Using anti-gp85 serum, an intracellular
rotein with an apparent mol wt of 92,000 daltons was im-
unoprecipitated from pulse-labeled infected chicken em-
ryo fibroblasts. The tryptic peptide elution pattern of this
rotein showed striking similarities to those obtained from
p85 and gp35: the four arginine-containing oligopeptides of
e 92,000-dalton protein were present in gp85 plus gp35.
hus, the 92,000-dalton protein appears to be the precursor
f the two viral glycoproteins. Using preferential labeling of
e 92,000-dalton polypeptide, it was determined that gp85
is located in the N-terminal position of the precursor molecule and gp35 is located in the C-terminal position. (31 refs)

78-3272 **Biochemical Properties of Avian Type-C Virus *gag* Gene-coded Proteins: Comparison with Structural Proteins Coded for at Analogous Positions Within the Mammalian Type-C Viral Genome.** (Eng) Reynolds, F. H. (Viral Oncology Program, NCI/Frederick Cancer Res. Center, P.O. Box B, Frederick, MD, 21501); Hanson, C. A.; Stephenson, J. R. *Virology* 86(1): 177-185; 1978.

The biochemical properties of the *gag* gene-coded structural proteins of two avian C-type virus isolates, avian myeloblastosis virus and the Prague strain of Rous sarcoma virus, were examined and compared with those of the previously characterized Rauscher murine leukemia virus *gag* gene proteins. The avian virus structural proteins had mol wts of 27,000, 19,000, 15,000, and 12,000 daltons. The results revealed striking similarities between proteins mapping at corresponding positions within the respective genomes of the avian and mammalian C-type viruses. These two groups of viruses may be evolutionarily related. (32 refs)

78-3273 **The Function of a Virus-coded Molecule Responsible for Malignancy.** (Eng) Bader, J. P. (Lab. Tumor Virus Genetics, NCI, NIH, Bethesda, MD, 20014). *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Disease, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 443-445; 1978.

The function of a Rous sarcoma virus (RSV) protein responsible for malignancy was investigated in cells infected with the RSV mutant RSV-BH-Ta, which induces morphological transformation when infected cells are maintained at 37 C but not at 41 C. Shift of RSV-BH-Ta-infected cells from 41 to 37 C resulted in morphological changes (intense cytoplasmic vacuolization, increase in cell size, increase in cell water) that were detectable within 30 min. These changes were independent of glucose uptake, hyaluronate synthesis, alkaline phosphatase, adenosine deaminase, or the large external transformation-sensitive protein. Of the components in the culture medium, only NaCl was necessary for vacuolization; Cl^- could be replaced by any of several anions without affecting vacuolization, but substitution of other cations for Na^+ resulted in distinguishable morphologic changes. Change in temperature to 41 C when Na^+ was the cation resulted in vacuole loss, but with other cations, the vacuoles failed to revert. These findings, combined with the results of staining tests using the cationic dye Neutral Red, suggested that the vacuoles are cation-specific organelles with channels extending to the cell surface. Vacuolated transformed cells had an increased Na^+ uptake but no difference in K^+ uptake compared with normal cells. This suggested that the vacuoles are responsible for increased Na^+ uptake. The transformation protein required neither RNA nor protein synthesis to function, but it did require glycosylation as part of its metabolic activation. (5 refs)

78-3274 **Absence of Adenosine Deaminase Activity in a Mammalian Cell Line Transformed by Rous Sarcoma Virus.** (Eng) Shipman, C. (Dental Res. Inst., Univ. Michigan, Ann Arbor, MI, 48109); Drach, J. C. *Science* 200(4346): 1163-1165; 1978.

An established line of mammalian cells (B-mix K-44/6) that lacks detectable adenosine deaminase (AD) activity is described. The B-mix K-44/6 cells were subcloned from a population of embryonic rat cells transformed in vitro by the Prague strain of Rous sarcoma virus. AD activity was measured in B-mix K-44/6, baby hamster kidney (B-mix K-44/6), BHK-21/4, and human epidermoid carcinoma (KB) cells. The respective AD activities were <0.004, 8.21, and 22.7 nanomoles substrate degraded/min/mg protein. Rates of deamination of arabinosyladenine (ara-A) and adenosine were compared for the three cell types grown in monolayer cultures in a medium essentially devoid of AD activity. Ara-A (100 μM) was deaminated to arabinosylhypoxanthine with a half-life of 2 hr in KB cells and 3 hr in BHK-21/4 cells; KB cell deamination could be detected after a 53-hr incubation period with B-mix K-44/6 cells when ara-A or adenosine were used. Similar findings were obtained with 105,000g cytosol preparations from B-mix K-44/6 cells. Since this line of cells can be readily adapted to growth in medium containing horse serum, a deaminase-free system not requiring the use of an AD inhibitor is available. (31 refs)

78-3275 **Genetic Control of Susceptibility of Mice to Rous Sarcoma Virus Tumorigenesis. II. Segregation Analysis of Strain A.SW-associated Resistance to Primary Tumor Induction.** (Eng) Whitmore, A. C. (Dept. Bacteriology and Immunology, Sch. Medicine, Univ. North Carolina at Chapel Hill, Chapel Hill, NC, 27514); Babcock, G. F.; Haughton, G. *J Immunol* 121(1): 213-220; 1978.

The inheritance of susceptibility of mice to primary sarcomas induced by neonatal injection of Rous sarcoma virus (RSV)-induced chicken tumor material was studied in segregating populations derived from F1 hybrids between the resistant strain A.SW (*H-2-8*) and the susceptible strains A/WySn, B10.A (both *H-2-a*), CBA/J (*H-2-8*), and C57BL/10 (*H-2b*). In F1 hybrids between A.SW and each of the four susceptible strains, res tance is apparently dominant. In the (A/WySn x A.SV F2, (A.SW x B10.A)F2, and (A.SW x CBA/J)F2 gene tions, tumor incidence was significantly associat with *H-2* type. *H-2-aa* and *H-2-kk* homozygot were as susceptible as A/WySn, B10.A, and CBA/J parent strain mice; and *H-2-88* homozygotes were as resistant A.SW parental mice. *H-2-as* and *H-2-ks* heterozygotes we of intermediate susceptibility. No evidence was se for association of susceptibility with three coat col genes or with sex. There was no maternal influence inheritance of susceptibility. In a (B10.LP x A.SW) C57BL/10 backcross generation, *H-2-sb* segregants we significantly more resistant to Rous tumorigenesis th were *H-2-bb* segregants. No influence of genes link to *agouti* or of X-linked genes was seen in this bac cross generation. When mice of high and low prima tumor incidence strains were immunized with t same allogeneic Rous sarcomas, resistant strains develope stronger cellular anti-Rous tumor immunity (as measured b the Winn lymphocyte-tumor cell transfer assay) than did sus ceptible strains. 78-3277 **Murine Rous-Sarcoma-specific Immunity Detected by Leukocyte Adherence Inhibition: Inhibitory Effect of Normal Serum.** (Eng) Wikstrand, C. J (Dept. Pathology, Duke Univ. Medical Center, Duke Univ. Durham, NC, 27710); Proctor, J. O.; Hartsell, S. C.; Haughton, G. *Int J Cancer* 21(5): 639-647; 1978.

The standard one-stage lymphocyte adherence inhibitio (LAI) assay was used to investigate cellular and humoral immune responses in the murine Rous sarcoma system. Significant cellular reactivity to Rous sarcoma antigen extracts wa detected when the responder peritoneal exudate cells (PEC were obtained from C57BL/10 ScSn mice bearing primar or transplanted Rous sarcomas or from immunized mice. N cellular reactivity to methylcholanthrene (MC)-induced tumor antigen extracts was observed. Similarly, specifi cell-mediated recognition of MC tumor antigen extracts wa demonstrated. Initial experiments to assess the role of serum components in the LAI assay demonstrated that fresh o frozen serum from normal C57BL/10 ScSn, B10.D2, or A/WySn mice (aged <6 wk or >7 mo) nonspecifically abrogated the specific loss of PEC adherence. 8-3281 **Role of B Cells in the Expression of Genetic Resistance to Growth of Rous Sarcoma in the Chicken.** (Eng) McBride, R. A. (Dept. Pathology, New York Medical Coll., Valhalla, NY, 10595); Watanabe, D. H.; chierman, L. W. *Eur J Immunol* 8(2): 147-149; 1978.

'o determine the possible role of antibody-forming cells (B ells) in the development and growth of Rous sarcoma, the ffects of neonatal bursectomy (Bx) on Rous sarcoma virus RSV)-inoculated genetically resistant and susceptible chickns were studied. The chickens were from two inbred lines hat differed with respect to the major histocompatibility omplex (MHC) antigens: G-B1 (susceptible to Rous saroma) and G-B2 (resistant). Newly hatched birds were Bx nd given 4 mg cyclophosphamide immediately and 2 days ater. At 5 wk of age, sera were tested for immunoglobulin; t 6 wk, tumors were induced by wing web injection of the chmidt-Ruppin strain of RSV. The Bx birds showed absent r only trace quantities of IgG and normal amounts of IgM. The rate of Rous sarcoma growth was greater among the Bx irds throughout the study period. Tumors induced in Bx and ıon-Bx G-B1 birds grew at a similar rate up to day 21, at vhich time tumor regression began to occur in some non-Bx irds. Rapidly growing tumors developed in all G-B1 birds nd Bx G-B2 birds, but in only 25% of non-Bx G-B2 birds. 3x G-B1 and Bx G-B2 birds showed a higher mortality rate han the non-Bx controls. The data indicate that Bx alters he expression of the resistance trait controlled by the R-Rs-1 ene in line G-B2 birds. It is likely that the delayed and weak esponse of some non-Bx G-B1 birds to Rous sarcoma, which ppears to be B cell-dependent, has a different basis than the nore vigorous early response displayed by non-Bx G-B2 irds. (22 refs)

78-3282 **Effects of Dexamethasone on the Morphogenesis of Two Mutants of Rous Sarcoma Virus.** (Eng) Ogura, H. (Dept. Biochemistry, Cancer Inst., Okayama Univ. Medical Sch., Okayama, Japan); Harms, E.; Rohrschneider, J. M.; Bauer, H. *Intervirology* 10(1): 1-10; 1978.

The effect of 10^{-6} or 10^{-5} M dexamethasone (DXM) on the Bryan high-titer strain of Rous sarcoma virus [BH RSV(-)Q, clone 3] and on *LA* 334, two replication-defective mutants of avian sarcoma virus, was investigated. Treatment of Japanese quail cells transformed by BH RSV(-)Q, clone 3, with DXM (either dose) resulted in the appearance of intracytoplasmic A-type particles; these particles were not present in the absence of DXM. The particles had an overall diameter of 65-75 nanometers, and they consisted of two concentric shells surrounding an electron-lucent central core 40-50 nanometers in diameter. Treatment with $> 10^{-5}$ M DXM caused cytotoxicity and no A-type particles were noted. Chick embryo cells (CEC) infected with the temperature-sensitive mutant *LA* 334, which is defective for both transformation and viral replication, showed an abnormal accumulation of viral core substances and aberrant budding at the nonpermissive temperature (41 C). CEC infected with *LA* 334 and treated with DXM exhibited a more extensive accumulation of abnormal budding without an increased release of viral particles. However, DXM did not lead to an abnormal morphogenesis of virus under permissive conditions. It is suggested that the effect of DXM is amplified in the viral replication-defective systems. (37 refs)

78-3283 **Proteins of Rous-associated Virus 61, an Avian Retrovirus: Common Precursor for Glycoproteins gp85 and gp35 and Use of Pactamycin to Map Translational Order of Proteins in the *gag*, *pol*, and *env* Genes.** (Eng) Shealy, D. J. (Biophysics Lab., Graduate Sch., Univ. Wisconsin-Madison, Madison, WI, 53706); Rueckert, R. R. *J Virol* 26(2): 380-388; 1978.

Chick embryo cells infected with Rous-associated virus 61 (RAV-61), a subgroup F virus, contained a precursorlike protein, pr90, that was specifically precipitated by antiserum against the envelope glycoproteins gp85 and gp35 of Rous sarcoma virus, strain Prague B. Tryptic peptide mapping showed that pr90 contained the tryptic sequences of both gp85 and gp35. Pactamycin mapping experiments indicated that the two glycoproteins are translated from the *env* gene messenger RNA (mRNA) in the order (5′) gp85-gp35. These experiments also indicated a translational order of p19-(p27,p12)-p15 for the *gag* proteins, which was the same as that obtained in pactamycin mapping studies of the precursor pr76 of avian myeloblastosis virus. Therefore, the stoichiometry of the RAV-61 core proteins was apparently unchanged when the virions were assembled in the presence of pactamycin. The reverse transcriptase proteins, unlike those of the *env* and *gag* genes, fell on the right side of the pactamycin map. This result is in agreement with the concept that most, if not all, of the reverse transcriptase protein is translated by a readthrough of the *gag*(*pol*) message, rather than by translation of a hypothetical *pol*-mRNA devoted solely to the synthesis of that protein. (34 refs)

78-3284 **Detection of Nucleotide Sequences Related to the Transforming Gene of the Avian Retrovirus in Normal Vertebral DNA (Meeting Abstract).** (Fre) Roussel, M. J. (Unite de Virologie, no. 102, INSERM, place de Verdun, 59045 Lille, France); Stehelin, D. *Bull Cancer (Paris)* 65(1): 39-40; 1978. (no refs)

78-3285 **Size Distribution of Globin Pre-mRNA in AEV Transformed Erythroblasts (Meeting Abstract).** (Eng) Therwath, A. (Institut de Recherche en Biologie Moleculaire, Tour 43, 2 Place Jussieu, F. 75021, Paris, France); Mengod, G.; Scherrer, K. *Bull Cancer (Paris)* 65(1): 32-33; 1978. (no refs)

78-3286 **Avian Myelocytomatosis and Erythroblastosis Viruses Lack the Transforming Gene *src* of Avian Sarcoma Viruses.** (Eng) Stehelin, D. (Virology Unit 102, Place de Verdun, 59045 Lille, France); Graf, T. *Cell* 13(4): 745-750; 1978.

Molecular hybridization experiments with complementary DNA specific for the detection of the *src* transforming gene of avian sarcoma viruses (ASV) showed that avian myelocytomatosis virus strain MC29 and avian erythroblastosis virus strain ES4 lacked nucleotide sequences related to the *src* gene. Furthermore, virus-transformed chicken fibroblasts and hematopoietic cells showed no enhanced level of transcription of the cellular nucleotide sequences related to the *src* gene. Thus, these two replication-defective viruses may contain their own transforming gene(s) or induce cellular genes unrelated to the *src*-like cellular sequences. (33 refs)

78-3287 **Avian Myeloblastosis Virus DNA Polymerase Directed Full-Length Globin and Procollagen Transcripts: Characterization of Template Specific Reaction Conditions (Meeting Abstract).** (Eng) Krueger, L. J. (NHLBI, NIH, Bethesda, MD, 20014); Anderson, W. F. *Fed Proc* 37(6): 1604; 1978. (no refs)

78-3288 **The Influence of Carbohydrate on the Antigenicity of the Envelope Glycoprotein of Avian Myeloblastosis Virus and B77 Avian Sarcoma Virus.** (Eng) Van Eldik, L. J. (Dept. Microbiology and Immunology, Duke Univ. Medical Center, Durham, NC, 27710); Paulson, J. C.; Green, R. W.; Smith, R. E. *Virology* 86(1): 193-204; 1978.

The immunological reactivity of the surface glycoproteins (gp85) of avian myeloblastosis virus (AMV) and B77 avian sarcoma virus was examined by competition radioimmunoassay (C-RIA). The influence of the protein and carbohydrate portions of the glycoprotein on the antigenic reactivity was investigated by systematic digestions of AMV gp85 with proteases and glycosidases. Digestion of AMV gp85 with trypsin, trypsin and chymotrypsin, or Pronase had no effect on the antigenicity detected in C-RIA's using rabbit antibody against AMV gp85. However, digestion of AMV gp85 with a mixture of neuraminidase, β-galactosidase, β-N-acetylglucosaminidase, and endo-β-N-acetylglucosaminidase eliminated the reactivity detected in C-RIA with the same antisera. Sequential digestion of AMV gp85 with various combinations of glycosidases indicated that removal of sialic residues had no effect on antigenicity and that remova of β-galactose and β-N-acetylglucosamine residue abolished antigenic reactivity. Furthermore, glycosidase digestion of ^{125}I-labeled AMV gp85 decreased the reactivity in direct RIA. Thus, the immunological reactivity of AMV gp85 depends upon an intact carbohydrate side chain. Digestion of AMV gp85 with proteases and glycosidases, followed by C-RIA using antibody against B77 gp85, showed that protease treatment resulted in a partial loss of antigenic reactivity. Treatment of B77 gp85 with proteases and glycosidases, followed by C-RIA using antibody prepared against B77 gp85, showed that protease treatment resulted in a partial loss of antigenic reactivity, glycosidase treatment in no loss of antigenic reactivity. 78-3289 **Structure of Avian Tumor Virus DNA Intermediates.** (Eng) Guntaka, R. V. (Dept. Microbiology, Coll. Physicians and Surgeons, Columbia Univ., New York, NY). *Biochem Biophys Res Commun* 82(1): 335-341; 1978.

The mechanism of conversion of virion RNA to double-stranded DNA in avian sarcoma virus (ASV)-infected duck embryo cells was studied. ASV-infected fibroblasts were fractionated, and the nucleic acids were extracted and centrifuged to equilibrium in an isopycnic Cs_2SO_4 gradient; in some cases, heat denaturation or treatment with alkali was performed before banding. The results indicated the presence of RNA-DNA duplexes consisting of DNA minus strands and virion RNA covalently linked to plus-strand DNA. Nucleic acids of the various pools were analyzed in neutral rate zonal sucrose gradients after heat denaturation and alkali igestion. The sedimentation profiles of all pools showed that ie minus-strand DNA consisted of molecules of complete ngth (28S) as well as one-fourth to one-third genome length 2S to 15S). The plus strands in pool I contained 8S DNA, ome of which were covalently linked to parental RNA. The lus strands of pool III consisted predominantly of 8S pieces nd some duplex molecules with single strand tails or gaps; ere were no free single-strand structures of either polarity. ool IV contained duplex viral DNA of genome size as well s duplex DNA of one-third to one-half length minus strands ase-paired with short plus strands. The data indicate that here is a covalent linkage between virion RNA and newly ynthesized plus-strand DNA and that plus-strand DNA ynthesis initiates at several discrete positions. (11 refs)

8-3290 **Synthesis and Processing of Avian Sarcoma Virus Glycoproteins.** (Eng) Hayman, M. (Can-er Res. Fund, P.O. Box 123, Lincoln's Inn Fields, London VC2A 3PX, England). *Virology* 85(2): 475-486; 1978.

vian sarcoma virus (ASV) glycoproteins gp85 and gp37 are ormed by proteolytic cleavage of a glycosylated precursor olypeptide, pr95, of mol wt 95,000. The intracellular site of ynthesis and cleavage of this precursor polypeptide was tudied in ASV B77-infected chick embryo fibroblasts. Folowing a 30-min pulse label, pr95 was found exclusively in he membrane fraction of infected cells. Of the other two recursor polypeptides, the *gag* precursor was located in both he membrane and cytoplasmic fractions, and the *gag-pol* preursor was located exclusively in the cytoplasmic fraction. ubfractionation of the membrane fraction revealed that pr95 vas associated with the rough endoplasmic reticulum, inlicating that it was synthesized on membrane-bound polyomes. Pulse-chase experiments demonstrated that pr95 was leaved within the membrane fraction, and further fractionaion indicated that this cleavage took place within the endolasmic reticulum of the cell. The cleavage products gp85 and p37 were then transported to the plasma membrane of the ell for incorporation into budding virus. These observations re discussed in relation to virus assembly. (18 refs)

8-3291 **Effect of Dibutyryl Cyclic AMP on Intracellular Levels of Avian Sarcoma Virus Specific NA.** (Eng) Guntaka, R. V. (Dept. Microbiology, Coll. hysicians and Surgeons, Columbia Univ., New York, NY, 0032); Weiner, A. J. *Nature* 274(5668): 274-276; 1978.

he effect of dibutyryl cyclic AMP (dbcAMP) on the inracellular levels of avian sarcoma virus (ASV)-specific RNA vas studied. Primary cultures of chick embryo fibroblasts CEF) were infected with ASV containing the transforming *src*) gene, and virus-specific RNA was monitored by nucleic cid hybridization. Max depression (75%-80%) in the levels f virus-specific RNA was observed after treatment of the cells for 8 hr with 250 μg/ml cAMP. Removal of dbcAMP from cultures after 8 hr completely reversed suppression in > 8-16 hr. There was a corresponding decrease in the levels of virus released into the medium after cAMP treatment. Similar results were obtained with different strains of ASV. When the experiments were carried out using transformation-defective (*src*-negative) ASV-infected cells, cAMP did not affect the levels of viral RNA. When CEF were infected with a temperature-sensitive ASV mutant, virus-specific RNA was specifically reduced in cells treated with cAMP only at the permissive temperature. In another experiment, *src* RNA was suppressed 9- to 10-fold by cRNA, whereas virus-specific RNA was suppressed only 4-fold. The data suggest that dbcAMP, in the presence of the *src* gene product, suppresses virus-specific RNA transcription by an unknown mechanism. (19 refs)

78-3292 **In Vitro Transcription of Reconstituted 35S RNA-tRNAtrp Template Primer Complexes by the Avian Oncornavirus DNA Polymerase: Effect of Temperature on the Size of the DNA Transcripts.** (Eng) Leis, J. P. (Dept. Surgery, Duke Univ. Medical Center, Durham, NC, 27710); Smith, R. E.; Dierks, P.; Parsons, J. T.; Collett, M. S.; Faras, A. J. *Virology* 85(1): 28-42; 1978.

The temperature dependence of the synthesis of long and short DNA transcripts from avian sarcoma virus 35S RNA-transferRNA-trp (RNA-tRNA-trp) template-primer complexes in vitro was studied. After 4 hr incubation at 15 C, about 70% of the DNA product synthesized was in the 100-nucleotide size class (DNA_{100}), whereas DNA molecules as large as 1,000 nucleotides in length were synthesized after 60 min incubation at 30 C. A precursor-product relationship between DNA_{100} and the larger DNA transcripts was established by pulse-chase experiments. Hybridization analysis indicated that the DNA_{100} synthesized at 15 C contains nucleotide sequences complementary to the 5′ end of the viral RNA genome. The longer tRNA-trp-initiated DNA transcripts synthesized at 30 C were found to contain at least some nucleotide sequences complementary to the 3′ end of the viral genome. It is suggested that when the tRNA-trp-primed DNA reaches the 5′-RNA terminus, it becomes single-stranded and then anneals to the redundant sequence at the 3′ end of the RNA, where it is elongated. The temperature-dependent step may be required to facilitate the alignment of the 5′ and 3′ termini of the viral genome to allow continued elongation of the 5′-initiated DNA_{100} transcripts at the 3′ end of the viral genome. (40 refs)

78-3293 **Viral Polyproteins in Chick Embryo Fibroblasts Infected with Avian Sarcoma Leukosis Viruses.** (Eng) Hayman, M. J. (Imperial Cancer Res. Fund, Lincoln's Inn Fields, P.O. Box 123, London WC2A 3 PX, England). *Virology* 85(1): 241-252; 1978.

The synthesis of virus-specific proteins was studied in chicken embryo fibroblasts infected with various isolates of avian sarcoma virus. Detergent extracts of pulse-labeled virus-infected cells were analyzed by immune precipitation. Three virus-specific precursor polyproteins with mol wts of 180,000 (180K), 95K, and 76K were detected, and additional immune precipitation experiments were performed to characterize the first two. The 76K polyprotein is the major precursor to the nonglycosylated *gag* proteins of the virion, and it has been extensively described previously. The 95K protein was precipitated by antiserum against a mixture of the two virion glycoproteins gp85 and gp37, and the 180K protein contained protein sequences in common with the virion polymerase and *gag* proteins. Additional pulse-chase experiments indicated that the 180K protein did not represent a precursor to the major 76K *gag* precursor polyprotein, although it could represent the precursor to the virion polymerase. It is probably synthesized as an occasional read-through product from the *gag* messenger RNA. The data indicate that the three precursor proteins are solely precursors to virion proteins and that they exist independently of the morphological phenotype of the cell. (43 refs)

78-3294 **Contrasting Characteristics of Marek's Disease Herpesvirus Isolated from Chickens with and Without Avian Leukosis Virus Infection.** (Eng) Campbell, W. F. (Dept. Microbiology, Mayo Clinic, Rochester, MN, 55901); Kufe, D. W.; Peters, W. P.; Spiegelman, S.; Frankel, J. W. *Intervirology* 10(1): 11-23; 1978.

The effect of avian leukosis virus (ALV) infection on Marek's disease herpesvirus (MDHV)-induced tumor development was studied. MDHV isolated from chickens free of naturally occurring ALV infection produced characteristic foci in both chicken embryo fibroblasts (CEF) and chicken kidney cells (CKC). MDHV-A, extracted from the feather follicle epithelium of chickens naturally infected with ALV, did not induce cytologic changes in CEF cultures, but did cause focus formation in CKC cultures. ALV was detected in MDHV-A, but not in MDHV preparations. MDHV and MDHV-A were then injected in ALV-free LSI-SPF chickens. MDHV-A elicited a high incidence of early mortality that was not accompanied by the gross tumor spectrum characteristic of Marek's disease, although extensive histologic lesions were present. The differences between MDHV and MDHV-A were not as striking in another line of ALV-free chickens (SPAFAS). In contrast, among conventional chickens with naturally occurring ALV infection, neither MDHV-A nor MDHV caused appreciable early mortality, although both resulted in gross tumor development. These findings indicate that the presence of ALV can influence the in vitro and in vivo characteristics of MDHV. However, they do not imply that MDHV required the presence of ALV to produce disease. (37 refs)

78-3295 **Characterization of an Apparently Nononcogenic Marek's Disease Virus.** (Eng) Schat, K. A. (Dept. Avian and Aquatic Animal Medicine, New York Stat Coll. Veterinary Medicine, Cornell Univ., Ithaca, NY 14853); Calnek, B. W. *J Natl Cancer Inst* 60(5): 1075-108 1978.

An apparently nononcogenic Marek's disease virus (MDV that can protect against MDV and against the non-virus producing MD tumor transplant, JMV, was isolated. Thi virus, SB, and a clone, SB-1, differed from pathogenic isolate in in vitro growth characteristics: failure to induce lymphomas or neural lesions, good growth in chick embryo fibroblasts (CEF) and chick kidney cultures, production o larger plaques in CEF and smaller plaques in CKC than th pathogenic viruses, and production of herpesvirus of turkey (HVT). Serologically, SB could be distinguished from MD and the avirulent HVT. SB failed to induce lesions characteristic of MD during a 6- to 11-wk experimental period. I addition, SB was nononcogenic in immunosuppressed chickens or in chickens inoculated with the virus in ovo. However SB did cause cytolytic infection. The term 'nononcogenic' rather than 'apathogenic' is proposed to class fy this and similar isolates. A total of 500 focus-forming units of SB protected S-strain and P-line chicken against intraarterial challenge with MDV at highl significant levels ($p < 0.005$ and $p < 0.01$, respectively) The lesion spectrum in the MD-positive, but vaccinate chickens was different from that in nonvaccinate birds. This suggests that SB vaccination provided a immune response at the level of transformation. SB-1 protected against JMV challenge at highly significant levels ($p <$ 0.0005) 7 or 14 days postvaccination. Protection was absen in SB-1 vaccinated birds challenged with a transmissible lymphoid tumor transplant, which suggests that the protectio against JMV was specific. (46 refs)

78-3296 **In Vitro Establishment of Marek's Disease Herpesvirus-transformed Productive and Nonproductive Lymphoblastoid Cell Lines.** (Eng) Munch, D. (Dept. Veterinary and Animal Sciences, Univ. Massachusetts, Amherst, MA, 01003); Hohlstein, L.; Sevoian, M. *Infect Immun* 20(1): 315-318; 1978.

Two Marek's disease herpesvirus (MDV)-transformed lymphoblastoid cell lines (JMV-1 and JM-1) were established in vitro. Cell line JMV-1 was established from peripheral JMV lymphoblasts from moribund chickens; it has been maintained in culture for 40 wk. Injection of JMV-1 cells into 1-day-old S-line chickens produced a disease that was indistinguishable from the fatal lymphoblastic leukemia produced by injection of whole blood from moribund JMV-infected chicks. Cell line JM-1 was produced from a MD lymphoma induced by the JM strain of MDV. It has been maintained as a suspension culture for 20 wk. Injection of JM-1 into 1-day-old susceptible P-line chickens resulted in the neural and visceral lymphomas characteristic of MD. Cocultivation with chicken embryo fibroblasts, attempts to rescue MDV from kidney cell cultures established from chickens inoculated with JMV-1 or JM-1, and immunofluorescent staining indicate that JMV-1 is a nonproductive line and JM-1 is a productive line. (6 refs)

78-3297 **Are Spleen Focus-forming Virus Sequences Related To Xenotropic Viruses and Expressed Specifically in Normal Erythroid Cells?** (Eng) Pragnell, I. B. (Beatson Inst. Cancer Res., Garscube Estate, Glasgow, England); McNab, A.; Harrison, P. R.; Osterag, W. *Nature* 272(5652): 456-458; 1978.

To study the role of the spleen focus-forming virus (SFFV) component of the Friend virus (FV) complex during erythroblastosis and subsequent erythroid cell transformation, an SFFV-specific complementary DNA (cDNA) probe was synthesized using FV released from transformed F4-6 cells. The SFFV-specific probe annealed > 80% to the 60S RNA of the FV complex and < 10% to the helper lymphatic leukemia virus (LLV) 70S RNA. Although total FV cDNA contained 25% xenotropic- and 33% AKR ecotropic-related sequences, these sequences were homologous to the helper LLV-related sequences and not to the SFFV cDNA. To test the hypothesis that SFFV specificity may lie in the viral transcription of sequences homologous to those involved in normal differentiation, nuclear RNA from normal erythroid cells was hybridized with the purified SSFV cDNA. These experiments detected sequences homologous to FV cDNA and SFFV cDNA in fetal liver RNA and total fetal nuclear RNA. The significance of these low levels of transcription of virus-specific information remains to be elucidated. (23 refs)

78-3298 **The Sizes of RNA Subunits Isolated from High and Low Leukaemogenic Friend Virus.** (Eng) Evenson, D. P. (Sloan-Kettering Inst. Cancer Res., New York, NY, 10021); Scotto, A.; Pla, D.; de Harven, E. *J Gen Virol* 39(3): 475-486; 1978.

The sizes of noncovalently linked RNA subunits isolated from highly leukemogenic Friend virus derived from the plasma of leukemic mice were compared with the sizes of RNA subunits isolated from low leukemogenic Friend virus grown in tissue culture by two RNA extraction procedures. Histograms derived from electron microscope measurements showed that the lengths of the RNA subunits from tissue culture virus (TCV) appeared to belong to different size classes that were similar regardless of whether the TCV RNA was isolated from 3-, 9-, 36-, or 72-hr cultures. The av sizes of each of these classes were approx 0.4, 0.7, and 1.1 μm, corresponding to mol wts of 0.5, 0.9, and 1.4 x 10^6, respectively. The sizes of noncovalently linked RNA subunits isolated from plasma virus (PV) were significantly larger than those of TCV RNA subunits, with the majority of the PV RNA subunits ranging from 1.4 to 2.5 μm in length, corresponding to mol wts of 1.8-3.0 x 10^6. The max PV RNA subunit length was about 3.5 μm. The histograms suggested that PV RNA may also have size classes, but they are not as evident as those for TCV RNA. Data obtained from sucrose gradient sedimentation of heat-denatured Friend leukemia virus RNA agreed with the electron microscope data. Since it can be expected that an intact, large RNA subunit is needed for max biological expression, the difference in leukemogenic potential observed between TCV and PV could be related to RNA subunit size. (29 refs)

78-3299 **Effect of Toyocamycin on Production of Friend Virus in Culture (Meeting Abstract).** (Fre) Mauchauffe, M. (Laboratoire d'Hematologie Experimentale, Hopital Saint-Louis, 75010 Paris, France); Tavitian, A.; Michel, M. L.; Larsen, C. J. *Bull Cancer (Paris)* 65(1): 36-37; 1978. (no refs)

78-3300 **Alteration of Cellular Ribonucleases Associated with Murine Oncogenic Virus Infection.** (Eng) Drake, W. P. (Section Immunology and Cell Biology, Cancer Res. Center, NIH, NCI, 3100 Wyman Park Drive, Baltimore, MD, 21211); Frazier, L. M.; Sidle, D.; Mardiney, M. R. *Biomedicine* 28(1): 24-28; 1978.

Changes in lymphocyte RNase activity were measured in male BALB/c mice infected with Friend leukemia virus (FLV) or Moloney sarcoma virus (MSV). Lymphocytes from mice infected with FLV possessed elevated levels of RNase activity within 8 days after infection. Mice infected with MSV demonstrated an analogous elevation of RNase activity within 7-9 days postinfection. Cellular RNase activity diminished in the FL model concomitant with the occurrence of significant numbers of erythroblasts in the peripheral blood, reaching a low around day 24 postinfection. RNase activity in lymphocytes from mice infected with MSV returned to normal 1-2 wk subsequent to host rejection of the tumor. It is concluded that elevation of RNase activity within the lymphocyte represents an early event in oncogenic viral infection in these tumor models. Elevation of RNase activity in a target not predestined to undergo immediate neoplastic transformation may represent a mechanism by which the cell can restrict neoplastic transformation. (15 refs)

78-3301 **Enhancing and Inhibiting Effects of Spleen Cells from Tumour-bearing Mice on Growth of Virus-induced Primary Sarcoma.** (Eng) Kimura, H. (Dept. Surgery, Inst. Pulmonary Cancer Res., Sch. Medicine, Chiba Univ., Inohana 1-8-1, Chiba 280, Japan); Aoki, T. *Br J Cancer* 37(4): 553-565; 1978.

The effects of adoptive transfer of spleen cells from tumor-bearing mice on the growth of Moloney murine sarcoma virus (M-MuSV)-induced primary tumors in BALB/c mice were investigated. The effects were bidirectional, depending on the time of lymphocyte injection. When spleen cells taken from tumor-bearing mice 12 days after M-MuSV inoculation were injected into recipient mice before M-MuSV inoculation, the appearance of tumors was significantly delayed and their incidence was reduced. However, when these lymphocytes were injected after the development of tumors in recipient mice, tumor growth was significantly enhanced. The data indicate that these inhibiting and enhancing effects are mediated mainly by T cells. (32 refs)

78-3302 **Syngeneic Tumor Enhancement of Moloney Sarcoma Accompanied by Decreased Immunity in the Regressors.** (Eng) Pasqualini, C. D. (Seccion Leucemia Experimental, Instituto de Investigaciones Hematologicas, Academia Nacional de Medicina, Las Heras 3092, 1425. Buenos Aires, Argentina); Mayer, A. M.; Piazzon, I. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 98-99; 1978.

Sc implantation of a glass cylinder containing Moloney sarcoma tissue in BALB/c mice increased in both tumor growth and mortality. This effect could be transferred by progressor serum. The corresponding regressor serum did not specifically inhibit tumor growth, compared with serum obtained after an sc transplant. Thus, the glass cylinder not only conditions for tumor enhancment, it also decreases tumor immunity. (6 refs)

78-3303 **Hydrophobic Binding Site(s) on Moloney-Murine Leukemia Virus P30.** (Eng) Swanson, S. K. (Dept. Medical Viral Oncology, Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263); Sulkowski, E.; Manly, K. F. *Virology* 85(1): 211-221; 1978.

The specificity of a hydrophobic binding site(s) on the Moloney murine leukemia virus (Mo-MuLV) p30 protein for binding various amino acid and hydrocarbon ligands was studied. Disrupted Mo-MuLV was applied to a decyl-agarose column and eluted with phosphate-buffered saline, NaCl, and 50% ethylene glycol. The p30 protein thus obtained showed no major change in its group-specific antigenic determinant. There was a positive correlation between the affinity of this protein for alkyl-substituted agarose and the chain length of the alkyl groups. This chain-length dependence of binding and the fact that p30 was eluted with 50% ethylene glycol but not with 1.0 M NaCl indicate that hydrophobic binding was involved. Significant purification of p30 was achieved by application of the disrupted virus to a hexyl-agarose column connected in tandem with an octyl-agarose column, followed by a separate elution of the octyl-agarose column with 50% ethylene glycol. p30 bound to the hydrophobic ligand β-hydroxy-γ-phenoxypropylagarose and to L-tryptophyl-L-tryptophan-agarose, but not to phenylalanine-agarose. This affinity can be explained by a general hydrophobic interaction. (33 refs)

78-3304 **Steroid Hormones Increase the Growth of MuLV in Rat Tumor XC Cells.** (Eng) Gautsch, J. W. (Dept. Cellular and Developmental Immunology, Scripps Clinic and Res. Foundation, 10666 N. Torrey Pines Road, La Jolla, CA, 92037); Bedigian, H. G.; Meier, H. *Virology* 83(2): 462-466; 1977.

The effects of various steroid hormones on the growth of Moloney murine leukemia virus (MuLV) in rat tumor XC cells were investigated. Infection of XC cells with 0.1 plaque-forming unit MuLV/cell resulted in the formation of syncytial plaques by 3-5 days; no syncytia formed in cultures that were not able to divide more than twice before confluency. Addition of 10^{-6} M dexamethasone (DXM) increased both the size and number of plaques. Various steroid hormones were then tested for enhancement of plaque formation at doses of 1 and 10 µg/ml. Corticosterone, hydrocortisone, prednisolone, and progesterone were as effective as DXM in inducing plaques; cortexolone, epiandrosterone, and aldosterone were slightly less effective; and allopregnane-3β,20β-diol, androstenedione, androsterone, cortisone, dehydroepiandrosterone, and estriol had minimal activity. Adrenosterone were slightly less effective; and allopregnane-3β,20β-diol, androstenedione, androsterone, cortisone, dehydroepiandrosterone, and estriol had minimal activity. Adrenosterone, deoxycorticosterone, estradiol, estrone, etiocolanolone, pregnanediol, and testosterone had no activity. This hormone-induced increase in virus production was specific for XC cells. It is suggested that the ability of steroid hormones to eliminate the restriction on the growth of MuLV in XC cells reflects a property of the hormone to alter only certain tissues or those in a certain metabolic state and that the ability of DXM to stimulate MuLV production results from action at the level of viral RNA transcription. (19 refs)

78-3305 **Leukemogenicity of Clonal Isolates of Murine Leukemia Viruses.** (Eng) Jolicoeur, P. (Institut de Recherches Cliniques de Montreal, 110 Ouest Avenue des Pins, Montreal, Quebec, Canada); Rosenberg, N.; Cotellessa, A.; Baltimore, D. *J Natl Cancer Inst* 60(6): 1473-1476; 1978.

The leukemogenicity of several clones of in vitro passaged N- and B-tropic BALB/c viruses and two in vitro-passaged clones of Moloney murine leukemia virus (M-MuLV) was examined. The five clones of B-tropic viruses tested induced lymphosarcoma when injected into neonatal BALB/c mice. The frequency of disease was similar to that observed when cloned M-MuLV stocks were used, but the latent period was longer. No pathologic changes were associated with injection of the N-tropic clones tested. B-tropic virus could be recovered from the spleens of leukemic mice and from inoculated, nonleukemic mice. No virus was recovered from mice inoculated with N-tropic clones, indicating that the N-tropic virus clones did not establish a persistent infection in the mice. This study supports previous findings that the naturally occurring B-tropic BALB/c mouse virus is oncogenic in its strain of origin. (23 refs)

78-3306 **MSV Tumor Resistance and Endogenous MuLV Expression in SJL Mice.** (Eng) Colombatti, A. (Netherlands Cancer Inst., Sarphatistraat 108, Amsterdam, Netherlands); D'Andrea, E.; De Rossi, A.; Collavo, D.; Biasi, G.; Chieco-Bianchi, L. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S. eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 94-97; 1978.

Although adult SJL mice do not develop tumors following injection of Moloney murine sarcoma virus (M-MSV), the embryonic cells of this strain are susceptible to transformation, and young SJL mice develop tumors when inoculated with full-strength virus. Genetic experiments suggest that a single dominant gene is responsible for resistance. Resistance was correlated with the expression of high titer endogenous ecotropic murine leukemia virus (MuLV). MuLV may block M-MSV viral receptors, or a cross-reacting natural immunity could account for the resistance of SJL adults. (8 refs)

78-3307 **Structure of the Genome of Moloney Murine Leukemia Virus: A Terminally Redundant Sequence.** (Eng) Coffin, J. M. (Cancer Res. Center, Tufts Univ. Sch. Medicine, Boston, MA, 02111); Hageman, T. C.; Maxam, A. M.; Haseltine, W. A. *Cell* 13(4): 761-773; 1978.

The genome of Moloney murine leukemia virus (Mo-MuLV) was analyzed by digestion with ribonuclease T1 and separation of the digestion products by two-dimensional gel electrophoresis. Thirty large oligonucleotides were isolated and characterized. Of these oligonucleotides, number 21 was present in twice the molar yield of the rest. The 30 oligonucleotides were mapped on the genome by determining their yields in various size classes of 3′ terminal fragments of Mo-MuLV RNA. The physical map thus obtained suggested that oligonucleotide 21 was present at both the 3′ and 5′ ends of the genome. The genome structure was confirmed by analyzing Mo-MuLV RNA oligonucleotides complementary to strong stop DNA, which was a copy of the 5′ terminal 134 nucleotides of the Mo-MuLV genome. Some of the RNA oligonucleotides protected from RNase digestion by hybridization to this DNA, including oligonucleotide 21, were present near both the 3′ and 5′ ends. Comparison of these results with the nucleotide sequence of strong stop DNA showed that there was a terminal redundancy of 49-60 nucleotides in the Mo-MuLV genome RNA. The role of the redundant sequence in the synthesis of proviral DNA is discussed. (24 refs)

78-3308 **Genetic Control of Moloney Virus Replication (Meeting Abstract).** (Fre) Gisselbrecht, S. (Laboratoire d'Immunologie et de Virologie des Tumeurs, INSERM U-152, Hopital Cochin, 75014 Paris, France). *Bull Cancer (Paris)* 65(1): 37; 1978. (no refs)

78-3309 **Murine Leukemia Viruses Containing an Approx 30 S RNA Subunit of Unknown Biological Activity, in Addition to the 38 S Subunit of the Viral Genome.** (Eng) Duesberg, P. H. (Dept. Molecular Biology and Virus Lab., Univ. California, Berkeley, CA, 94720); Scolnick, E. M. *Virology* 83(1): 211-216; 1977.

The detection of a 30S RNA species in (1) Kirsten murine leukemia virus (Ki-MLV) propagated in NIH 3T3 clone 1 cells and (2) Moloney MLV (Mo-MLV) propagated in chronically infected mouse thymus-bone marrow cells (line TB) is reported. The morphology of the cell lines propagating these viruses was indistinguishable from that of uninfected controls. The 30S species existed in addition to the 38S virion RNA. Both the 30S and 38S RNA had the ability to form 50S-70S RNA complexes and to be packaged by virus particles. The size of the Ki-MLV 30S RNA was judged to be 2 x 10^6 daltons based on its electrophoretic mobility; the size of the 30S RNA in Mo-MLV was slightly larger. Since both viruses can exist even if they contain only 38S RNA, it appears that the small RNA species is not an essential component of the viral genome. It is suggested that the 30S RNA is derived from a defective virus unrelated to MLV. (21 refs)

78-3310 **Expression of a Surface Antigen Associated with the Gross Virus by Cells Infected with the Radiation Leukemia Murine Virus (RadLV-Rs) (Meeting Abstract).** (Fre) Gerlier, D. (Centre Leon Berard, 69373 Lyon Cedex 2, France); Guillemain, B.; Dore, J. F.; Duplan, J. F. *Bull Cancer (Paris)* 65(1): 32; 1978. (no refs)

78-3311 **Endogenous Virus Antigens of Murine Lymphoblastoid Cell Lines.** (Eng) Wise, K. (Dept. Microbiology, Univ. Alabama in Birmingham, Birmingham, AL, 35294); Acton, R. *Protides Biol Fluid Proc Collo* 25: 707-714; 1977.

Several lymphoblastoid cell lines were examined for the presence of the endogenous murine leukemia virus (MuLV)-related cell surface antigens gp70 and the Gross cell-surface antigen (GCSA). The AKR thymus-derived BW5147 line expressed relatively large amounts of gp70 (as recognized by anti-gp70 antiserum), as did EL4G+ cells; normal B6 splenocytes showed only low levels of reactivity. The EL4 line expressed reduced amounts of surface gp70, and the incomplete inhibition seen in the absorption curve indicates that gp 70 present on these cells may contain only a portion of the determinants recognized by this system. The antiserum reacted with a cell membrane component with a mol wt of 70,000 and additional material in the range of 40-50,000 daltons. Limited proteolysis suggested that the latter material represented gp70 degradation products. The effect of infection with vesicular stomatitis virus on the expression of cell surface components was investigated in BW5147 and EL4G+ cells. Although no effect on Thy-1, H-2Kk, and gp70 surface components was observed, a marked selective increase in GCSA expression was noted in both lines. (18 refs)

78-3312 **Cell-Free Synthesis of a Precursor Polyprotein Containing Both gag and pol Gene Products by Rauscher Murine Leukemia Virus 35S RNA.** (Eng) Murphy, E. C. (Dept. Biology, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Kopchick, J. J.; Watson, K. F.; Arlinghaus, R. B. *Cell* 13(2): 359-369; 1978.

Evidence is presented that Rauscher murine leukemia virus (RLV) reverse transcriptase (RT) shares tryptic peptides with a 200,000-dalton polypeptide synthesized in vitro from RLV 35S RNA. The latter is identical in its tryptic maps to the *gag*- and *pol*-related polyprotein precursor (Pr200gag-pol) observed in RLV-infected cells. Nine of 11 methionine-containing tryptic peptides found in an anti-RT-precipitable 80,000-dalton virion polypeptide (p80pol) were contained in Pr200gag-pol. In addition, virion p80pol comigrated in sodium dodecyl sulfate-polyacrylamide gels with the major polypeptide found in partially purified preparations of active RT. The in vitro synthesized 200,000-dalton polypeptide was identical to intracellular Pr200gag-pol as determined by comparing ion-exchange profiles of methionine-labeled tryptic peptides. The frequency of the in vitro synthesis of Pr200gag-pol was 1/25 to 1/20 that of the combined synthesis of the RLV 65,000- and 75,000-dalton *gag* precursors. A similar ratio of Pr200gag-pol to Pr65gag and Pr80gag has been observed in virus-infected cells. Thus, 35S viral genomic RNA is a messenger RNA for both *gag* and *pol* gene products. In experiments in which the arginine in the cell-free reaction mixture was replaced by canavanine, protein synthesis was inhibited approx 50% and the major product comigrated with Pr80gag. These findings indicated that the usual termination signal occurs after the translation of Pr80gag and that Pr65gag is derived from Pr80gag by in vitro processing. The Pr200gag-pol may result from an occasional read-through (5% frequency) of a single termination codon at the end of the *gag* gene. (34 refs)

78-3313 **Phagocytosis of Red Blood Cells from Rauscher Leukemia Virus-infected Mice by Macrophages from Normal Syngeneic Mice.** (Eng) Knyszynski, A. (Section Biological Ultrastructure, Weizmann Inst. Science, Rehovot, Israel); Leibovich, S. J.; Danon, D. *J Reticuloendothel Soc* 23(4): 243-251; 1978.

The mechanism by which mouse macrophages interact with RBC from normal and Rauscher leukemia virus (RLV)-infected syngeneic SWR mice was studied in vitro. The "young" but not the "old" RBC from normal mice were phagocytized, whereas both "old" and abnormal "young" cells from RLV-infected mice were usually phagocytized. Incubation of the RBC from RLV-infected mice at 37 C in the presence of neuraminidase did not affect phagocytosis of these cells, but trypsin treatment generally decreased phagocytosis. Adsorption of fetal calf serum with unfractionated or young RLV RBC from RLV-infected mice markedly reduced the phagocytosis of the young RBC. The level of phagocytosis of RBC by mineral oil- or thioglycollate-stimulated peritoneal macrophages was considerably lower than that of unstimulated macrophages. Trypsin treatment of the macrophages almost completely eliminated their capacity to recognize and phagocytize RBC from infected mice. The data indicate that macrophages from normal animals recognize and phagocytize RBC from RLV-infected mice in vitro and that the recognition process depends on the presence of trypsin-sensitive receptors on the surfaces of the macrophages. It would appear that the defense mechanism that prevents the accumulation of deteriorated RBC in the circulation is in charge of the first-line defense mechanism against the development of Rauscher virus leukemia. (22 refs)

(Lab. de Virologie et de Culture de Tissus, Institut Gustave-Roussy, 94800 Villejuif, France); Leibovitch, S.; Athan, E. *Bull Cancer (Paris)* 65(1): 36; 1978. (no refs)

78-3315 **Serological and Biochemical Characterization of the Mouse Mammary Tumor Virus with Localization of p10.** (Eng) Cardiff, R. D. (Dept. Pathology, Sch. Medicine, Univ. California, Davis, CA, 95616); Puentes, M.

J.; Young, L. J.; Smith, G. H.; Teramoto, Y. A.; Altrock, B. W.; Pratt, T. S. *Virology* 85(1): 157-167; 1978.

Antisera against the five major mouse mammary tumor virus (MMTV) polypeptides (gp52, gp36, p28, p14, and p10) were characterized, and the immunological relationship between the virion and subvirion particles was studied. Antisera against p10, gp52, gp36, and p28 precipitated primarily their own antigens, and antiserum against whole virion (anti-MMTV) precipitated gp52, gp36, p28, and p10. Anti-p14 precipitated primarily p28 and p10 rather than p14. p14 was not precipitated by any of the antisera. In a radioimmunoassay, anti-p10 did not precipitate intact iodinated MMTV at any dilution, anti-p28 and anti-p14 produced some precipitation at low dilutions, and anti-MMTV, anti-gp52, and anti-gp36 precipitated the intact virions. These data were confirmed by immunodiffusion assay. Virions, cores, bald particles, and A particles contained p28 and p10 reactivity. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis revealed that p28 and p10 were the major polypeptides in virions and bald particles, but that p10 was reduced in the cores. No mature MMTV polypeptides were identified in the A particles. A salt-detergent extraction for hydrophobic proteins indicated that p10 was hydrophobic and lipophilic. The data suggest that gp52 and gp36 are on the envelope surface, that p28 and p14 are core polypeptides, and that p10 is probably membrane-associated. A model of MMTV maturation is suggested in which p10 links the nucleocapsid to the envelope. (28 refs)

78-3316 **Induction of Mammary Tumors in C57BL/Haag Female Mice by a Low Oncogenic Mammary Tumor Virus.** (Eng) Vlahakis, G. (Gene Regulation Section, Lab. Molecular Biology, NCI, NIH, Bethesda, MD, 20014); Chopra, H. C.; Sawdon, M. R. *Int J Cancer* 21(5): 648-651; 1978.

Newborn C57BL/Haag mice, a substrain that is negative for murine mammary tumor virus (MuMTV), were foster-nursed by a DD strain mother to ensure the introduction of MuMTV into the substrain. (DD strain mice have a high spontaneous mammary tumor incidence). The foster-nursed litter, designated C57BL/HaagfDDF$_1$, was then inbred until the F_4 generation to give a total of 87 females. The overall mammary tumor incidence in the C57BL/HaagfDD line was 62.1%, and the av age at tumor appearance was 20.1 mo. Tumors developed in 5/6 F_1, 19/37 F_2, 27/41 F_3, and 3/3 F_4 mice. Electron microscopy revealed B particles in the tumors, providing additional evidence for the transmission of DD MuMTV. The MuMTV's of DD and RIII mice may be related, since both albino strains originated in Europe, develop pregnancy-dependent mammary tumors, and carry black and agouti genes. (18 refs)

78-3317 **Expression of MuMTV-Related Antigens in Normal and Malignant Human Mammary Epithelial Cells (Meeting Abstract).** (Eng) Yang, N. S. (Michigan Cancer Foundation, Detroit, MI, 48201); Furmanski, P. *Fed Proc* 37(6): 1747; 1978. (no refs)

78-3318 **Effect of a Mouse Mammary Tumor Virus-derived Protein Vaccine on Primary Tumor Development in Mice.** (Eng) Creemers, P. (Tumor Virology Branch, REP Insts., Organization Health Res. TNO, 151 Lange Kleiweg, Rijswijk, ZH, Netherlands); Ouwehand, J.; Bentvelzen, P. *J Natl Cancer Inst* 60(6): 1461-1466; 1978.

The effect of murine mammary tumor virus (MuMTV)-derived protein vaccines on spontaneous tumor development was determined in GR, BALB/cfC3H, BALB/c, and C3Hf mice. Approx 60% of the protein fractions in the vaccines consisted of the major viral membrane glycoprotein gp52. Sc injection of 10 μg MuMTV-S-derived vaccine significantly delayed the appearance of primary mammary tumors in GR and BALB/cfC3H mice (strains with high incidences of mammary cancer). In BALB/c and C3Hf mice (which have moderate tumor incidences at an advanced age), this treatment resulted in a slight and substantial acceleration, respectively, of primary tumor development. The induced cellular immune reactivity for vaccination was stronger in the GR strain than in the BALB/c strain. Antibody titers to tumor cells were also higher in this strain. The influence of different vaccination schemes with an MuMTV-O-derived protein vaccine on primary tumor development was studied in BALB/cfC3H mice. The vaccine was precipitated on alum before it was injected sc. A dose of 10 μg vaccine resulted in a 61% decrease in tumor incidence. Two or five additional booster injections with 1 μg protein vaccine had no beneficial effect, although the amount of antibody was increased after the booster injections. (29 refs)

78-3319 **Structural Components of Mouse Mammary Tumor Virus. II. Isolation and Purification of Virion Polypeptides.** (Eng) Yagi, M. J. (Dept. Neoplastic Diseases, Mount Sinai Sch. Medicine, New York, NY, 10029); Stutzman, R. E.; Robertson, B. H.; Compans, R. W. *J Virol* 26(2): 448-456; 1978.

Mouse mammary tumor virus (MMTV) glycoproteins and nonglycosylated polypeptides, which were obtained from a BALB/cfC3H/Crgl mouse mammary tumor cell line, were purified by preparative sodium dodecyl sulfate-polyacrylamide gel electrophoresis. Primary amino groups were labeled with fluorescamine to enable visualization of MMTV polypeptides in the gels. Protein bands were sliced from the gels and eluted with 90%-95% recovery. Eight MMTV polypeptides, including three of the major viral components and five minor proteins, were obtained routinely. Double-diffusion assays and immunoelectrophoresis confirmed the retention of antigenicity identical to that of untreated MMTV virions.

Antisera from MMTV-free BALB/c mice immunized with these purified proteins reacted with the polypeptide immunogen as well as with detergent-disrupted MMTV virions from mouse milk or cell culture. Double-diffusion assays using the specific mouse antisera failed to detect any cross-reactivity among the isolated polypeptides. A hemagglutination-inhibition assay demonstrated that the ability of MMTV virions to inhibit the hemagglutinating properties of influenza virus resided in the glycosylated polypeptides gp52, gp37.7, and gp33. (21 refs)

78-3320 **Radioimmunoassays That Demonstrate Type-specific and Group-specific Antigenic Reactivities for the Major Internal Structural Protein of Murine Mammary Tumor Viruses.** (Eng) Teramoto, Y. A. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD, 20014); Schlom, J. *Cancer Res* 38(7): 1990-1995; 1978.

The 28,000-dalton (p28) major structural polypeptide of mouse mammary tumor virus (MMTV) was isolated and used to develop a highly sensitive and specific radioimmunoassay. Under conditions of limiting antibody in competitive-binding assays, as little as 50 picograms of purified p28, as well as disrupted MMTV virions and mammary tumor extracts, competed specifically with ^{125}I-labeled MMTV p28. The p28 polypeptide was further shown to contain both group-specific and type-specific antigenic determinants, thus allowing for further differentiation of various MMTV strains. By using this radioimmunoassay for MMTV p28 together with previously established radioimmunoassays for MMTV 52,000-dalton glycoprotein, levels of MMTV gene expression can now be analyzed in terms of both viral glycoproteins and nonglycoproteins. This type of comparison is important in light of recent evidence of the noncoordinate polypeptide chain initiation of glycosylated vs nonglycosylated MMTV proteins in infected cells. These combined radioimmunoassays should further clarify MMTV replication and gene expression in murine mammary tumors. (38 refs)

78-3321 **Isolation of Separate Precursor Polypeptides for the Mouse Mammary Tumor Virus Glycoproteins and Nonglycoproteins.** (Eng) Schochetman, G. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Long, C. W.; Oroszlan, S.; Arthur, L.; Fine, D. L. *Virology* 85(1): 168-174; 1978.

Monospecific antisera to the major glycoproteins (gp52 and gp36) and the major nonglycoprotein (p27) of murine mammary tumor virus (MMTV) were used in conjunction with tryptic peptide fingerprinting to isolate an intracellular MMTV precursor polypeptide to p27. All three antisera precipitated polypeptides of about 75,000 daltons; proteins with mol wt of 160,000 (H-1) and 48,000 (H-2) were also precipitated. Polypeptide gPr 75, which was precipitated by anti-gp-52 and anti-gp-36 sera, has been shown to be glycosylated and to be the precursor to gp52 and gp36. Polypeptide Pr75, which was precipitated by anti-p27 serum, had not been isolated previously, and it was not precipitated by normal rabbit serum. Pr75 bound to single-stranded DNA (ssDNA) and was easily separated from gPr75 by ssDNA-Sepharose column chromatography. Analysis of the tryptic peptide fingerprints of the virion proteins and precursor polypeptides showed that gPr75 contained the tryptic peptides of only gp52 and gp36, either of which bound to ssDNA. Fingerprints of the Pr75 precursor revealed the tryptic peptides of p14 and p27. Thus, at least p27 and p14 are derived from Pr75, which is distinct from gPr75. (15 refs)

78-3322 **Synthesis of Mouse Mammary Tumor Virus Ribonucleic Acid in Isolated Nuclei from Cultured Mammary Tumor Cells.** (Eng) Stallcup, M. R. (Dept. Biochemistry and Biophysics, Univ. California, San Francisco, CA, 94143); Ring, J.; Yamamoto, K. R. *Biochemistry (Washington)* 17(8): 1515-1521; 1978.

Procedures were designed to characterize the cell-free synthesis of mammary tumor virus (MTV) RNA in nuclei isolated from murine mammary carcinoma (GR) cells. The nuclei were incubated under conditions in which all three endogenous RNA polymerases were active. RNA synthesized in vitro was distinguished from preexisting nuclear RNA by labeling the in vitro products with ^{3}H-cytosine triphosphate; the level of MTV RNA synthesis was measured by molecular hybridization with unlabeled viral DNA. Synthesis required the addition of nucleoside triphosphates and was inhibited 90% by 10 μg/ml actinomycin D. Pretreatment of GR cells with dexamethasone had no significant effect on the amount of total RNA synthesis in isolated nuclei. In contrast, synthesis of MTV RNA was stimulated 10- to 20-fold in nuclei from dexamethasone-treated cells relative to untreated control nuclei. In vitro viral RNA synthesis was inhibited by 97% following exposure of the nuclei to 0.3 μg/μl α-amanitin, suggesting that this synthesis is carried out exclusively by RNA polymerase II. The fraction of total RNA synthesis that was viral specific (about 0.2%-0.4% in nuclei from dexamethasone-treated cells and 0.01%-0.03% in controls) was similar to that detected in pulse labeled RNA from whole GR cells in culture. This procedure appears to avoid artifacts noted in other in vitro transcription systems. (54 refs)

78-3323 **The Specificity of Neutralizing Antibodies to Feline Leukaemia Viruses.** (Eng) Russell, P. H. (ICRF Tumour Immunology Unit, Dept. Zoology, Univ. Coll. London, London W.C.1., England); Jarrett, O. *Int J Cancer* 21(6): 768-778; 1978.

The specificity of virus-neutralizing antibodies to feline leukemia virus (FeLV) of subgroups A, B, and C was investigated. The FeLV-A isolates were monotypic, but there was antigenic variation among the isolates of subgroups B and C. There was also considerable cross-reactivity between subgroups, especially between subgroups A and C. It is concluded that subgroup classification based on interference did not correspond with neutralizing behavior for subgroups B and C. (24 refs)

78-3324 **Feline Oncornavirus-associated Cell Membrane Antigen: Evidence for an Immunologically Crossreactive Feline Sarcoma Virus-coded Protein.** (Eng) Stephenson, J. R. (Lab. RNA Tumor Viruses, NCI, Bethesda, MD 20014); Khan, A. S.; Sliski, A. H.; Essex, M. *Proc Natl Acad Sci USA* 74(12): 5608-5612; 1977.

The nature of the feline oncornavirus-associated cell membrane antigen (FOCMA) was investigated. Mink and rat cells nonproductively transformed by feline sarcoma virus (FeSV) expressed FOCMA as well as the 5′-terminal feline leukemia virus (FeLV) *gag* gene proteins p15 and p12. Both nonproducer lines were negative for FeLV gp70, p30, and p10. Feline lymphoma cells, including those from several tumors that lacked detectable levels of FeLV structural protein expression, were all FOCMA-positive. In the two nonproducer cell lines, FeLV p15 and p12 expression was associated with 25,000 and 80,000-100,000 mol wt proteins, as determined by agarose gel filtration under denaturing conditions. The 80,000-100,000 mol wt protein also exhibited antigenic determinants in common with FOCMA. Immunoprecipitation and polyacrylamide gel electrophoresis of the 80,000-100,000 mol wt protein indicated the presence of a 65,000 mol wt protein that exhibited only FOCMA determinants. These findings indicate that the 80,000-100,000 mol wt protein represents a precursor containing p15, p12, and FOCMA and that it is subject to posttranslational cleavage, giving rise to a 25,000 mol wt protein containing p15 and p12 and a second protein containing FOCMA antigenic determinants. The demonstration of FOCMA expression in naturally occurring feline tumors, even in the absence of FeLV structural proteins, and the results of previous studies suggest that FOCMA represents a transformation-specific protein. (19 refs.)

78-3325 **Influence of Antisera to Oncornavirus Glycoprotein (gp71) on Infections of Cats with Feline Leukemia Virus.** (Eng) de Noronha, F. (Dept. Pathology, Cornell Univ., Ithaca, NY, 14850); Schafer, W.; Essex, M.; Bolognesi, D. P. *Virology* 85(2): 617-621; 1978.

To determine if there is an interspecies cross-reactivity in in vivo serum therapy studies, 6-mo-old kittens that had been inoculated 6 days previously with feline leukemia virus (FeLV) were treated with either normal goat serum, goat antiserum to FeLV, or goat antiserum to purified Friend leukemia virus (FLV) gp71. All the kittens (9/9) treated with normal goat serum became persistently viremic, but 6/8 given anti-FeLV and 6/9 given anti-FLV gp71 resisted the persistent viremia. Only 1/9 animals that remained viremic by 101 days postinfection had detectable virus neutralizing antibody titers, but 11/12 animals that did not become viremic developed significant levels of this antibody. At 114 days postinfection, two virus-free animals initially treated with anti-FeLV and two virus-free animals initially treated with anti-FLV gp71 were challenged with FeLV. None of the four developed persistent viremia. These findings suggest that viral antigens, in particular their interspecies determinants, can be used as targets for immunotherapeutic regimens for the prevention and control of diseases induced by oncornaviruses. (Laboratoire d'Immunologie et Virologie des Tumeurs, INSERM U. 152, Hopital Cochin, 27, rue du Faubourg Saint-Jacques, Paris, 14, France); Deshayes, L.; Parodi, A. L. *Bull Cancer (Paris)* 65(1): 38-39; 1978. (no refs)

78-3328 **Biosynthesis of Bovine Leukemia Virus (BLV) Major Internal Protein (p24) in Infected Cells and *X. laevis* Oocytes Microinjected with BLV 60-70S RNA.** (Eng) Ghysdael, J. (Departement de Biologie Moleculaire, Universite de Bruxelles, Brussels, Belgium); Hubert, E.; Cleuter, Y. *Arch Int Physiol Biochim* 85(5): 978-979; 1977.

Xenopus laevis oocytes were inoculated with 60S-70S bovine leukemia virus (BLV) RNA and used to study the biosynthesis of p24, the major internal protein of p24. The oocytes were labeled with ^{3}H-leucine and either frozen immediately or incubated in culture medium containing an excess of unlabeled leucine for up to 2 wk. Lysates were prepared from the different batches, and p24-related sequences were precipitated with anti-p24 serum. Electrophoresis and fluorography indicated that p24 was generated by proteolytic cleavage of a 68,000 to 70,000-dalton precursor polypeptide . The same high-mol-wt precursor was observed when 60S-70S BLV RNA was translated in a reticulocyte lysate treated with micrococca nuclease; however, p24 was not generated in this system. The cleavage pattern in *X. laevis* oocytes was the same as that in fetal lamb kidney cells infected with and producing BLV; cleavage in the oocytes was much slower than that in infected cells. (5 refs)

78-3329 **Further Characterization of a Herpesvirus-positive Orangutan Cell Line and Comparative Aspects of In Vitro Transformation with Lymphotropic Old World Primate Herpesviruses.** (Eng) Rabin, H. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Neubauer, R. H.; Hopkins, R. F.; Nonoyama, M. *Int J Cancer* 21(6): 762-767; 1978.

The orangutan suspension cell line, CP-81, and its associated B-cell-tropic virus, *Herpesvirus pongo*, were characterized. CP-81 lacked myeloid markers of lysozyme activity and phagocytosis, but it was positive for lymphocytic N-alkaline phosphatase activity and it released *H. pongo*. *H. pongo* had 30%-40% DNA homology with Epstein-Barr virus (EBV) and it was present at two to three genome copies per CP-81 cell. Gibbon cell lines transformed by *H. pongo* (733/*H. pongo*), EBV (733/EBV), and *H. papio* (733/H. papio) were established. Cells from all three lines stained positively for virus-associated intracellular antigens. 733/*H. papio* and 733/EBV cells were fibrinolytically active, but only 733/EBV cells produced interferon and lymphotoxin. 733/EBV and 733/*H. papio* cells had the normal diploid chromosome number of gibbon cells, whereas 733/*H. pongo* cells were hypodiploid due to an apparent loss of the Y chromosome. Gibbon lymphocytes transformed by *H. pongo* and EBV and transplanted intracranially (ic) into nude mice showed success rates of 75% and 45%, respectively. Transplants of similar cells transformed by *H. papio* were only 10% successful. None of these lines were able to be transplanted sc, and none manifested a high degree of colony formation in 0.33% agarose. CP-81 cells could be transplanted both ic (100% success rate) and sc (70%), and they showed a relatively high degree of colony formation in agarose. EBV-transformed marmoset cells, line B95-8, could be transplanted ic (66%) but not sc, and they had a low but significant ability to grow in agarose. *H. papio*-transformed baboon cells, line 594S, could be transplanted ic (25%) but not sc, and they grew at very low levels in agarose. (25 refs)

78-3330 **Relatedness Between Genomes of Gibbon Type C Oncornaviruses and the Neoplastic Diseases with Which They are Associated (Meeting Abstract).** (Eng) Sun, L. (Univ. California, Davis, CA, 95616); Kawakami, T. G. *Fed Proc* 37(6): 1745; 1978. (no refs)

78-3332 **Isolation of Foamy Virus Type II from Hematopoietic Cells of Baboons with Hemoblastoses and Those of Healthy Animals.** (Eng) Agrba, V. Z. (Inst. Experimental Pathology and Therapy, USSR Acad. Medical Sciences, Gora Trapezija, Sukhumi, USSR); Kokosa, L. V.; Cuvirov, G. N.; Bierwolf, D.; Widmaier, R.; Graffi, A.; Lapin, B. A.; Sangulia, I. A.; Rudolph, M. *Arch Geschwulstforsch* 48(2): 97-111; 1978.

Sixteen monolayer and 5 suspension cultures of hematopoietic (bone marrow, spleen, and lymph node) cells from 2 baboon embryos and 14 baboons aged 1 day to 18.6 yr were studied for foamy virus type II. Four animals were healthy, and 12 had hemoblastoses. Giant cells and foamy virus type II were found in 13 monolayer and 3 suspension cultures of 12 animals. The positive animals included both healthy ones and those with hemoblastoses. Foamy virus was also found in one 1-hr-old baboon, which is indicative of the intrauterine transmission of foamy virus. Some animals also appeared to be contaminated by foamy virus type I. The findings are in agreement with those of other researchers. The role played by foamy virus is not known. (20 refs)

78-3333 **Pathologic and Immunologic Response to the Baboon Endogenous Virus and Its Pseudotype.** (Eng) Kalter, S. S. (Southwest Foundation Res. and Education, San Antonio, TX); Heberling, R. L.; Eichberg, J. W.; Boenig, D. M.; Cummins, L. B. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 100-102; 1978.

The pathologic and immunologic response of various animals to baboon xenotropic endogenous virus (BaEV) and its murine sarcoma pseudotype [MSV(BaEV)] was determined. BaEV did not produce tumors in a wide variety of nonhuman primates, beagle dogs, hamsters, or nude mice. BaEV was isolated from organ explants of beagle dogs inoculated in utero. MSV(BaEV) produced tumors in newborn dogs, chimpanzees, white-lipped and cottontop marmosets, and baboons (following intracerebral inoculation). Cell-mediated immunity to both viruses was demonstrated mainly by a blastogenic response. (15 refs)

78-3334 **Regulation of Viral Functions in SV40 Transformed Mouse Cells (Meeting Abstract).** (Eng)

Zouzias, D. C. (New York Univ. Medical Sch., New York, NY, 10016); Basilico, C. *Fed Proc* 37(6): 1746; 1978. (no refs)

78-3335 **Transformation of Skin Fibroblast Cells of a Cystinotic Patient by Simian Virus 40: Evidence for an Establishment of a Permanent Cell Clone Which Retains the Original Metabolic Defect.** (Eng) Darai, G. (Institut fur Medizinische Virologie, Universitat Heidelberg, Im Neuenheimer Feld 324, D-6900 Heidelberg 1, W. Germany); Harms, E.; Flugel, R. M.; Braun, R.; Munk, K. *Cytobiologie* 17(1): 42-50; 1978.

Simian virus 40 (SV40) was used to transform human cystinotic cells (line HCF-132) in order to obtain a human cystinotic cell line capable of indefinite growth in vitro. The cell clones thus established (SV-HCF-132) showed an epithelial-like morphology, unlike the parental cells, which showed a fibroblastoid morphology. More than 80% of the SV-HCF-132 cells contained SV40 tumor (T) antigen within their nuclei. The parental HCF-132 cells did not show any immunofluorescence typical of T antigen. The transformed cell clones grew in soft agar, but the parental HCF-132 cells did not. The doubling time during exponential growth was 24 hr for SV-HCF-132 and 72 hr for HCF-132 cells; the saturation density was higher for the former cells. The modal chromosome number in transformed clone No. 6 was 68. The cystine content of clone No. 6 was as high as that of the parental cells. The high cystine concentration did not change after 40 passages of the SV-HCF-132 cells. In addition, SV40-transformed skin fibroblasts from a patient with Fanconi's anemia and SV40-transformed cells from a healthy child had normal cystine levels. Thus, the high cystine content of SV-HCF-132 cells was not due to the effects of long-term culturing or to viral transformation per se. The growth characteristics of the SV-HCF-132 clones make them suitable for the large-scale preparation of cellular constituents, eg, lysosomes, which seem to be affected in cystinotic patients. 78-3337 **The 5′-Terminal Leader Sequence of Late 16 S mRNA from Cells Infected with Simian Virus 40.** (Eng) Ghosh, P. K. (Dept. Medicine, Yale Univ. Sch. Medicine, New Haven, CT, 06510); Reddy, V. B.; Swinscoe, J.; Choudary, P. V.; Lebowitz, P.; Weissman, S. M. *J Biol Chem* 253(10): 3643-3647; 1978.

The relationship of the late 16S messenger RNA (mRNA) leader of simian virus 40 (SV40) to the major structural protein (VP1) coding segment of this mRNA was investigated. This 16S mRNA directs the synthesis of VP1, and it is composed of a leader sequence of 203 nucleotides joined to a transcript that contains all the codons for VP1. The leader is transcribed from DNA between 0.723 and 0.762 map unit, but the VP1 coding transcript is copied from DNA from 0.94 to 0.17 map unit. The leader sequence joins the transcript of the coding region at a position 42 nucleotides upstream from the initiator codon for VP1 by a 3′:5′-phosphodiester linkage. Longer leader sequences also occur in a portion of SV40 late mRNA. (31 refs)

78-3338 **The Structure of SV40 Chromatin.** (Eng) Zentgraf, H. (Inst. Virus Res., German Cancer Res. Center, Heidelberg, W. Germany); Keller, W.; Muller, U. *Philos Trans R Soc Lond [Biol]* 283(997): 299-303; 1978.

Simian virus 40 (SV40) nucleoprotein complexes were studied by electron microscopy. Depending on the isolation procedure, SV40 chromatin has two different conformations: complexes isolated in the presence of 0.15 M NaCl had compact globular structures, but those isolated in the presence of 0.6 M NaCl had the typical beads-on-a-string appearance of the primary nucleofilament. Concomitant with this structural change was a variation in the histone pattern and sedimentation behavior of the complexes: with 0.15 M NaCl, the isolated complexes contained both the nucleosomal histones and histone H1, and they sedimented in sucrose gradients at 70S. Increasing the ionic strength to 0.6 M NaCl resulted in the removal of histone H1 from the complexes and in a decrease of the sedimentation coefficient to 40S. DNA-relaxing enzyme was associated with the SV40 nucleoprotein complexes. The number of superhelical turns in DNA was identical in both types of complex. Therefore, the transition from the condensed to the open structure of viral chromatin does not require a change in the topological winding number of its DNA. (23 refs)

78-3339 **Nucleotide Sequence of the Simian Virus 40 *Hind*-K Restriction Fragment.** (Eng) Rogiers, R. (Laboratorium voor Moleculaire Biologie, Rijksuniversiteit Gent, Ledeganckstraat, 35, B-9000 Ghent, Belgium); Van de Voorde, A.; Soeda, E.; Fiers, W. *Eur J Biochem* 85(1): 205-224; 1978.

The nucleotide sequence of the restriction fragment *Hind*-K, which represents 4.2% of the simian virus 40 (SV40) genome and is located near the middle of the late region, is reported. The sequence was established by analysis of transcription products, synthesized by using *Escherichia coli* RNA polymerase and nucleoside triphosphates, one of which was (α-^{32}P)-labeled. Strand assignment was possible by hybridization of asymmetric, labeled transcripts of total SV40 DNA to filter-bound *Hind*-K fragments. The sequence was confirmed by using direct DNA-sequencing methods. The *Hind*-K sequence is 219 base pairs long. The message strand is particularly rich in adenosine (39%) and purines. The nucleotide sequence could unambiguously be translated into an amino acid sequence, and the N-terminal codon of the viral protein VP1 could be identified. The amino-terminal part of VP1 is rich in proline and lysine. The nucleotide sequence of *Hind*-K also codes for the carboxyl-terminal part of the viral protein VP2 and VP3 genes, which partly overlap the VP1 gene. (52 refs)

78-3340 **Nucleotide Sequence of Part of the Simian Virus 40 *Hind*-D Restriction Fragment: The Presumed Initiation Region of the VP2 Gene.** (Eng) Ysebaert, M. (Laboratorium voor Moleculaire Biologie, Fakulteit der Wetenschappen, Rijksuniversiteit te Gent, K. Lod Ledeganckstraat 35, B-9000 Ghent, Belgium); Van Heuverswyn, H.; Van de Voorde, A.; Fiers, W. *Eur J Biochem* 85(1): 195-204; 1978.

The nucleotide sequence at the beginning of the restriction fragment *Hind*-D, from simian virus 40 (SV40) DNA was derived by partial chemical degradation of (5′-^{32}P)-labeled restriction fragments followed by analysis on polyacrylamide gel. The *Hind/Hae* fragment, a product of double digestion, corresponds to 2.65% of the SV40 genome and is adjacent to the previously published *Hind*-L and *Hind*-M segments. The sequence is 140 nucleotides long, and it contains an ATG codon that probably represents the initiation codon of the VP2 protein. This codon is preceded by an untranslated region that is characterized by an alternation of (dA+dT)-rich and (dG+dC)-rich blocks. It seems likely that these remarkable alternations have an important, but as yet unknown, biological meaning. (37 refs)

78-3341 **The Structure of a Cloned Substituted SV40 Genome.** (Eng) Oren, M. (Dept. Virology, Weizmann Inst. Science, Rehovot, Israel); Lavi, S.; Winocour, E. *Virology* 85(2): 404-421; 1978.

The structure of the DNA of a cloned host-substituted simian virus 40 (SV40) variant was investigated by restriction endonuclease cleavage mapping and hybridization of the cleavage products to monkey and wild-type SV40 DNA's. The circular DNA of this variant comprised four tandemly repeated segments, each of which consisted of covalently linked viral and monkey DNA sequences. Only two of the repeated subunits were of equal size. A detailed cleavage map of the variant genome is presented. The viral sequences in each of the four subunits were derived from the portion of the wild-type SV40 genome (0.59-0.73 map unit) that contains the origin of replication. Monkey DNA sequences of the reiterated type were linked to monkey DNA sequences of the less-reiterated or nonreiterated type in three subunits. The monkey DNA sequences in the fourth subunit were predominantly of the reiterated type. Hybridization experiments to clarify the relationship between the host DNA sequences in the cloned variant and those in other independently derived substituted SV40 populations indicated that some populations share both reiterated and nonreiterated host DNA sequences, whereas other populations share only the reiterated sequences. (35 refs)

78-3342 **Use of Defective SV40 Replicons for the Propagation of Prokaryotic DNA in Mammalian Cells.** (Eng) Fareed, G. C. (Dept. Microbiology and Immunology, Molecular Biology Inst., Univ. California at Los Angeles, Los Angeles, CA, 90024); Upcroft, P. *Miami Winter Symp* 14: 49-71; 1977.

The use of simian virus 40 (SV40) as vector for the propagation of specific prokaryotic DNA segments in mammalian cells is discussed. In one experiment, segments of 520 and 2,400 base pairs from the immunity region of bacteriophage λ were linked in vitro to SV40 vectors and propagated in monkey cells in the presence of added helper, wild-type SV40 DNA. In both recombinant genomes, the structure of λ DNA segment was largely unchanged after serial passage in monkey cells. In another experiment, an *Escherichia coli* DNA segment was inserted after *Eco*RI and *Hpa*II cleavages, into a deletion in the late gene region of SV40. It was propagated with the aid of a helper early gene SV40 mutant. This purified chimeric DNA, which contained the SV40 genetic information needed for cellular transformation and for viral DNA replication, was used to transform rat embryo cells and to transfect monkey kidney cells. Preliminary findings on the structure of the viral and bacterial DNA sequences in these cell lines are summarized. (16 refs)

78-3343 **Interaction of SV40 T Antigen with Selected Regions of SV40 DNA.** (Eng) Livingston, D. M. (Sidney Farber Cancer Inst., Boston, MA); Tenen, D. G.; Jessel, D.; Haines, L. L.; Woodard, V.; Modest, A. P.; Maxam, A.; Hudson, J. *Miami Winter Symp* 14: 103-119; 1977.

Simian virus 40 (SV40) tumor (T) antigen was isolated from the SV40-transformed human cell line SV80 and examined for binding to SV40 DNA. The antigen was extracted from purified nuclei of mass cultures and purified by fractionation, chromatography, and glycerol gradient sedimentation. Electrophoresis demonstrated a species migrating with a mol wt of approx 90,000 daltons. Binding studies indicated that the antigen bound to virtually all molecules in a fixed aliquot of labeled SV40 DNA I. The question of whether T antigen binds selectively to one or more specific regions of the SV40 genome was investigated using restriction endonuclease fragments of the genome. Preferred T-antigen binding sites were noted in regions identified by *Hin* d(II + III) fragments A, B, and C. Repetition of these experiments using T antigen isolated from SV40-transformed Chinese hamster lung cells gave similar results. Thus, the binding phenomena are not specific to T antigen from a given SV40-transformed cell line. The interaction of T antigen with one or more sets of sequences within the SV40 early region might reflect a role for this protein in transcription. (38 refs)

78-3344 **Isolation and Characterization of SV40 T Antigen.** (Rus) Drise, O. B. (Cancer Res. Center, Acad. Medical Sciences USSR, Moscow, USSR); Voskoboinik, A. D.; Polotskaya, A. V.; Shlyankevich, M. A.; Shapot, V. S. *Biokhimiia* 42(8): 1471-1477; 1977.

The purification and isolation of functionally active simian virus 40 (SV40) T antigen are presented. SV40-induced hamster tumors were homogenized and subjected to several purification procedures. Precipitation with ammonium sulfate resulted in 5-fold purification, diethylaminoethylcellulose chromatography in 60-fold purification, electrophoresis in polyacrylamide gel in 460-fold purification, and immunoadsorption of foreign proteins with immunoadsorption of foreign proteins with immunochemical filters in 1,300- to 1,600-fold purification. Upon electrophoresis, T antigen was separated into three fractions with mol wts of 100,000, 200,000, and 400,000, of which only the 200,000 mol wt fraction showed endonuclease activity. (25 refs.)

78-3345 **Antigenic Similarity Between Extracts of Fetal Cells and Simian Virus 40 Tumor Specific Surface Antigens (Meeting Abstract).** (Eng) Weppner, W. A. (Univ. South Alabama, Mobile, AL, 36688); Coggin, J. H. *Fed Proc* 37(6): 1561; 1978. (1 ref)

78-3346 **Amino Acid Sequence Homology Between Polyoma and SV40 Tumour Antigens Deduced from Nucleotide Sequences.** (Eng) Friedmann, T. (Dept. Pediatrics, Sch. Medicine, Univ. California at San Diego, La Jolla, CA, 92093); Doolittle, R. F.; Walter, G. *Nature* 274(5668): 291-293; 1978.

Evidence for amino acid sequence homology between polyoma and simian virus 40 (SV40) tumor antigens was obtained from a study of the nucleotide sequences in the viral DNA's. The deduced amino acid sequences for both polyoma and SV40 tumor antigens were identical in 49/174 positions, the most striking homologies occurring from amino acids 1 to 58 and from amino acids 119 to 159. Eight of the 11 cysteine residues in polyoma virus could be aligned with 8/11 SV40 cysteine residues. The major homology domain from amino acids 1 to 58 was located in the region common to T (mol wt 100,000) and t (mol wt 20,000) antigens (0.65 to 0.60 map units). The second domain from amino acids 119 to 159 was located in the coding region unique for t antigen (0.60 to 0.55 map units). The latter region contained the highly conserved cysteine clusters. The sequence Cys X Cys X X Cys, found in both viral DNA's, also occurs in the α and β subunits of all members of the glycoprotein hormone family, in two immunoglobulin γ-chains, and in one kind of keratin. Another sequence in the Bowman-Birk soybean trypsin inhibitor closely resembles sequences in SV40 t antigen and polyoma t antigen. The data suggest that SV40 and polyoma virus have a common evolutionary origin and that the tertiary structures of their t and T antigens are similar. (20 refs)

78-3347 **Construction of a Viable SV40 Variant Containing Two Functional Origins of DNA Replication.** (Eng) Shenk, T. (Dept. Microbiology, Univ. Connecticut Health Center, Farmington, CT, 06032). *Cell* 13(4): 791-798; 1978.

Viable insertion variants of simian virus 40 (SV40) that contained two functional origins of DNA replication (Or) were constructed. The variants were made by introducing, at 0.175 on the SV40 map, a segment of DNA containing the viral Or. (The region near 0.67 map unit on the SV40 genome contains the original viral Or.) Pulse-labeling and electron microscopy demonstrated that the second Or was functional. The distribution of radioactivity in pulse-labeled closed-circular SV40 (I) DNA was dramatically altered in the variants compared with the parental virus. Electron microscopic examination of viral replicative intermediates indicated that there was one initiation site for DNA synthesis in the parental genome but two in the variant. A deletion could be introduced in the variant that inactivated the original Or. The resulting mutant could still be propagated, and its DNA replication originated at the site of the newly inserted Or. Therefore, the viral genome can tolerate the addition of new nucleotide segments at 0.175 map unit. Other small DNA segments could presumably be inserted at this site and propagated as part of a fully viable genome. (25 refs)

78-3348 **Structural Studies on Defective SV40 Variants Substituted with Monkey DNA Sequences (Meeting Abstract).** (Eng) Wakamiya, T. (Lab. Molecular Biology and Biochemistry, NCI, NIH, Bethesda, MD, 20014); McCutchan, T.; Singer, M.; Rosenberg, M. *Fed Proc* 37(6): 1736; 1978. (no refs)

78-3349 **Construction and Biological Activities of Deletion Mutants of Simian Virus 40.** (Eng) Nathans, D. (Dept. Microbiology, Johns Hopkins Univ. Sch. Medicine, Baltimore, MD, 21205); Lai, C. J.; Scott, W. A.; Brockman, W. W.; Adler, S. P. *Miami Winter Symp* 14: 1-10; 1977.

Experiments on the properties of mutants containing deletions of either the early or late region of the simian virus 40 (SV40) genome are summarized. SV40 deletion mutants were cloned from serially passed virus stocks or constructed by enzymatic manipulation of the DNA. Some of the mutants produced detectable short polypeptides derived from SV40-coded proteins. Mutants in the late region were used to map the junctions between the D and B/C genes. The results suggest that the D gene may overlap with the B/C gene and that, within the *Hin*-E segment preceding the B/C gene proper, there is a signal required for expression of the B/C gene. Late region mutants were also used to define SV40 functions that require only the early or A gene. Mutants lacking portions of both late genes but with an intact early genomic segment were able to induce T antigen in infected cells, replicate their DNA in the absence of helper virus, stimulate thymidine incorporation in cellular DNA, and transform mouse and hamster cells. A cell fusion-complementation rescue procedure was used to show that cells transformed by late deletion mutants contained the mutant genome. Deletion mutants lacking substantial portions of the early genomic region, including those segments where temperature-sensitive A mutants map, lacked all the above activities. (14 refs)

78-3350 **Properties of Simian Virus 40 and BK Virus Tumor Antigens from Productively Infected and Transformed Cells.** (Eng) Simmons, D. T. (Lab. Biology Viruses, Natl. Inst. Allergy and Infectious Diseases, NIH, Bethesda, MD, 20014); Takemoto, K. K.; Martin, M. A. *Virology* 85(1): 137-145; 1978.

Simian virus 40 (SV40)-specific tumor antigen (T Ag) and BK virus (BKV) T Ag immunoprecipitated from lytically infected and transformed cells were studied. T Ag from SV40-transformed hamster cells had the same electrophoretic mobility in acrylamide gel as the 97,000 (97K)-dalton T Ag isolated from SV40-infected monkey cells. Smaller mol wt forms of SV40 T Ag (76K-90K) were also readily isolated by immunoprecipitation from extracts of infected monkey cells. Experiments using the protease inhibitor L-l-tosylmide-2-phenylethylchloromethyl ketone (TPCK) indicated that the smaller species of SV40 T Ag were derived from the 97K or 94K protein by proteolytic cleavage during their purification from the infected cells. SV40 T Ag could be immunoprecipitated in the presence of either anti-SV40 T serum or anti-BKV T serum, and the various mol wt forms of SV40 T Ag observed with anti-SV40 T serum were also precipitated with anti-BKV T serum. The synthesis of BKV T Ag occurred at significantly later times after infection than did the corresponding SV40 protein. The largest species of labeled SV40 T Ag (97K) comigrated with the largest BKV T Ag in acrylamide gels, as did the 94K protein form of each viral T Ag. The data suggest that the proteins with an apparent mol wt of 97K were the monomer forms of the T Ag in the SV40-infected or -transformed cells and BKV-infected human cells. (24 refs)

78-3351 **Studies of Adenovirus and SV40 Genes Required for In Vitro Transformation.** (Eng) van der Eb, A. J. (Sylvius Labs., Univ. Leiden, Leiden, Netherlands); Lupker, J. H.; Maat, J.; Abrahams, P.; Jochemsen, H.; Houweling, A.; Fiers, W.; Mulder, C.; van Ormondt, H.; de Waard, A. *Miami Winter Symp* 14: 121-137; 1977.

The transforming ability of various adenovirus and simian virus 40 (SV40) restriction fragments was investigated. With adenovirus 2 (Ad2) and Ad5 DNA, fragments with transforming activity were obtained with the restriction endonucleases *Eco* RI, *Bam*HI, and *Hsu* I; these fragments represent the left-terminal fragments of both viral DNA's. Rat cells transformed by *Eco* RI and *Bam* fragments had T-antigen fluorescent patterns similar to those of cells transformed by intact virus. However, cells transformed by the 7% *Hsu* I G fragment of Ad5 DNA had an abnormal distribution T antigen. Examination of five clones of *Hsu* I G transformed rat cells indicated these cells contained viral DNA sequences homologous to 75%-85% of this fragment. Thus, a segment as small as 5.5%-6% of the viral genome contains information for the maintenance of transformation. The proteins coded for by this section of the genome were identified. RNA selected by hybridization to total Ad5 DNA was translated into at least seven polypeptides and five of these [51,000 (51K), 48K, 42K, 38K, and 14K] were encoded by the 7% *Hsu* I G fragment. Further experiments indicated that *Hpa* I fragment E, which contains the left terminal 4.3% of Ad5 DNA, also had transforming activity. Studies of Ad12, Ad3, and Ad7 DNA indicated that a terminal fragment of Ad3 and Ad7, obtained with endonuclease R. *Sma* I, and an *Eco* RI C fragment from Ad12 had transforming activity. The latter fragment also induced tumors upon its injection into newborn hamsters. Studies of SV40 DNA indicated that the 74% *Eco* RI/*Hap* II A, the 59% *Bam* HI/*Hap* II A, endo R. *Eco* RI, *Bgl* I, and *Eco* RI/Taq I A fragments contained transforming activity. (16 refs)

78-3352 **SV40-Adenovirus 2 Hybrid Viruses.** (Eng) Sambrook, J. (Cold Spring Harbor Lab., P.O. Box 100, Cold Spring Harbor, NY, 11524). *Miami Winter Symp* 14: 139-179; 1977.

The isolation of hybrid viruses whose defective 5- to 6-kilobase genomes contain both simian virus 40 DNA and adenovirus 2 (Ad2) DNA is described. Cellular recombination enzymes were used during the construction of these hybrids. The structure of arrangement of these genomes is complex, but in the simplest case, restriction endonuclease digestion and hybridization indicated that the Ad2 DNA was present as a continuous block with a max size of 2.8 kilobases. Different hybrids contained sequences derived from different segments of the Ad2 genome. (33 refs)

78-3353 **Starting Points of Adenovirus DNA Replication (Meeting Abstract).** (Ger) Winnacker, E. L. (Inst. fur Biochemie, Univ. Munchen, Karlstrasse 23, D-8000 Munich 2, W. Germany) Reiter, T.; Weingartner, B. *Hoppe Seylers Z Physiol Chem* 359(3): 339; 1978. (1 ref)

78-3354 **Transfer RNA Methylation in Adenovirus 2 Infected KB Cells (Meeting Abstract).** (Eng) Varricchio, F. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Sehulster, L.; Raska, K. *Fed Proc* 37(6): 1733; 1978. (no refs)

78-3355 **Intracellular Forms of Adenovirus DNA. VII. Excision of Viral Sequences from Cellular DNA in Adenovirus Type 2-infected KB Cells.** (Eng) Baczko, K. (NIH, Bethesda, MD, 20014); Neumann, R.; Doerfler, W. *Virology* 85(2): 557-567; 1978.

Viral sequences were excised from the high-mol-wt DNA of adenovirus type 2 (Ad2)-infected KB cells with three restriction endonucleases of different specificities, *Eco* RI, *Bam* HI, and *Sal* I. Analysis of the restriction endonuclease fragments by gel electrophoresis and DNA-DNA hybridization revealed viral DNA sequences that did not coincide in size with the respective Ad2 virion DNA restriction endonuclease fragments. After cleavage with *Bam* HI or *Sal* I, some viral sequences found in the fragments were larger than the largest virion DNA fragments. Of the viral DNA sequences found after cleavage with *Eco* RI, none was larger than the *Eco* RI A fragment with a mol wt of 13 x 10^6 daltons, which indicated that intact Ad2 DNA does not have a simple oligomeric structure. These results suggest that Ad2 DNA is integrated into cellular DNA in fragments rather than as the intact molecule. This integration pattern is consistent with previous observations that the right end of Ad2 DNA is overrepresented in the 50S-90S class of viral DNA. (19 refs)

78-3356 **Two Regions of the Adenovirus 2 Genome Specify Families of Late Polysomal RNAs Containing Common Sequences.** (Eng) McGrogan, M. (Dept. Pathology, Div. Biology and Biomedical Sciences, Washington Univ. Sch. Medicine, St. Louis, MO, 63110); Raskas, H. J. *Proc Natl Acad Sci USA* 75(2): 625-629; 1978.

Late cytoplasmic RNA's specified by two regions of the adenovirus 2 genome (39.3-51.8 and 70.7-83.4 map units) were analyzed by size fractionation of poly(A)-polysomal ^{3}H-RNA and subsequent hybridization to DNA fragments. Both regions encoded RNA's whose sequence content exceeded the coding capacity of the region. These multiple transcripts are likely to function as messenger RNA's (mRNAs), because they were present on polyribosomes. The messenger DNA segment 39.3-51.8 specified 27S, 22S, and 18S RNA's. The genome sites specifying these three size classes were determined by hybridizations with seven different DNA fragments from this genome region. The 3′ termini of all three size classes were specified by sequences near a common site, position 50.1. The 27S RNA included sequences beginning near 39.3, the 22S RNA sequences from 41.0, and the 18S RNA sequences from approx 45.3 on the unit genome. A second family of four RNA's was transcribed from 70.7-83.4. These 28S, 22S, 18S, and 16S RNA's have a relationship similar to the RNA's transcribed from 39.3-51.8. Sequences near the 5′ ends of these four size classes were specified by different genome sites. However, the 3′ termini of all four classes were localized near map position 80.4. The synthesis of families of RNA may allow the translation of multiple polypeptides from a genome segment that has only one terminator site for mRNA synthesis. (23 refs)

78-3357 **Mapping of Adenovirus Late Promoters with Nascent Mercurated RNA.** (Eng) Weinmann, R. (Wistar Inst. Anatomy and Biology, 36th St. at Spruce, Philadelphia, PA, 19104); Aiello, L. O. *Proc Natl Acad Sci USA* 75(4): 1662-1666; 1978.

Nascent RNA molecules were labeled in vivo and elongated in vitro by incubation of the isolated nuclei in the presence of mercurated nucleotides. The RNA molecules initiated and labeled in vivo and elongated in vitro were then selectively purified on a thiopropyl 6-B Sepharose affinity column. The procedure was free of artifacts, since the addition of mercurated nucleotides and retention of the elongated RNAs on the affinity column were mediated by the endogenous RNA polymerase II (nucleoside triphosphate:RNA nucleotidyltransferase; artificial aggregates did not form), sensitive to actinomycin D, and dependent on the presence of all four ribonucleotide triphosphates. This general procedure was applied to the mapping of viral promoters late after adenovirus 2 infection of HeLa cells. RNA purified as described was hybridized to restriction enzyme fragments attached to nitrocellulose filters. The 5′ ends of the nascent RNA chains were located in coordinates 9.5-17 for a rightward transcript, 0-25 for a leftward transcript, and possibly 60-70 for a second rightward transcript. These locations differed clearly from those of the early promoters, suggesting that the transition from early to late functions is controlled at the transcriptional level. (38 refs)

78-3358 **Adenovirus Type 12 Tumor Antigen. I. Separation from DNA Polymerase α and Immunoprecipitation of Tumor-Antigen Polypeptides.** (Eng) Biron, K. K. (Cancer Res. Center, Univ. North Carolina, Chapel Hill, NC, 27514); Morrongiello, M. P.; Raskova, J.; Raska, K. *Virology* 85(2): 464-474; 1978.

Adenovirus type 12 (Ad12) tumor (T) antigen was extracted from Ad12-transformed baby hamster kidney BHK21 cells and partially purified (> 500-fold) by chromatography on double-stranded DNA-cellulose. The antigen contained DNA polymerase α activity that was partially inhibited by antibodies in immune ascitic fluid. The DNA polymerase and T antigen could be completely separated by chromatography on single-stranded DNA-cellulose, to which T antigen did not bind. Antibodies reacting with T antigen had no inhibitory effect on the isolated DNA polymerase. The fraction eluting in the void volume of a single-stranded DNA-cellulose column containing > 1200-fold-purified T antigen markedly stimulated the activity of DNA polymerase α with the native DNA template; with the activated DNA template, the stimulation was less prominent. This stimulation was not significantly affected by T-antigen-reactive antibodies. An analogous fraction of control BHK21 cells had similar stimulatory effects on the isolated DNA polymerase α, indicating that the stimulatory activity is probably not attributable to T antigen. Of the T-antigen polypeptides immunoprecipitated from the > 1200-fold-purified preparations by antibodies from tumor-bearing hamsters, one was identified as a major peptide of mol wt 50,000, the other as a minor species of mol wt 11,000. (35 refs)

78-3359 **Deletions and Insertions in Adenovirus Type 12 DNA after Viral Replication in Vero Cells.** (Eng) Werner, G. (Institut fur Klinische Virologie, Universitat Erlangen-Nurnberg, Loschgestrasse 7, 852 Erlangen, W. Germany); Zur Hausen, H. *Virology* 86(1): 66-77; 1978.

The adaptation of adenovirus type 12 (Ad12; Huie strain) to growth in Vero cells is reported. Infection of the cells was achieved at low input multiplicities; the cells were negative for the expression of simian virus 40 and BK virus T antigens. In contrast to wild-type virus, the adapted virus formed plaques in Vero cells and replicated in primary African green monkey kidney cells. The DNA of the adapted virus was analyzed by heteroduplex mapping, contour length measurement, and cleavage by the restriction endonucleases Bam HI, Eco RI, and Sma I. The data indicated that replication of Ad12 in Vero cells resulted in the accumulation of at least five groups of deletion mutants containing deletions between 0.5 and 1.5 x 10^6 in mol wt. Plaque purification of the same virus preparations in Vero cells resulted in the loss of most of the deleted molecules and permitted the identification of DNA insertions in fragment E of the Bam HI digest. These insertions ranged between 1.2 and 1.8 x 10^5 in mol wt and appeared to represent host cell-specific sequences. (32 refs)

78-3360 **Radiometric Detection of Herpes Simplex Viruses.** (Eng) D'Antonio, N. L. (Johns Hopkins Medical Insts., Baltimore, MD); Tsan, M. F.; Griffin, D. E.; Charache, P. A.; Wagner, H. N. *J Nucl Med* 19(2): 185-190; 1978.

Two radiometric procedures for the detection of herpes simplex virus (HSV) infections were developed in which ^{3}H-thymidine or ^{125}I-iododeoxyuridine is used. Cells infected with HSV-1 or -2 showed increased thymidine incorporation after infection, as did mouse brains infected with HSV-1. Similar results were observed with iododeoxyuridine. This increased incorporation could be inhibited by preneutralization of the virions with immune serum. (22 refs)

78-3361 **Characteristics of the Fc Receptor Induced by Herpes Simplex Virus.** (Eng) Costa, J (Lab. Pathology, Div. Cancer Biology and Diagnosis, NCI, NIH, Bethesda, MD, 20014); Yee, C.; Nakamura, Y.; Rabson, A. *Intervirology* 10(1): 32-39; 1978.

The Fc receptor induced in various cell lines by herpes simplex virus type 1 (HSV-1) from human trigeminal ganglion and HSV- 2 (strain MS) was studied. The 7S early antigen rosette assay revealed that within 20 hr of infection, WI-38 diploid human fibroblasts, Molt lymphoblastoid cells, Y-79 human retinoblastoma cells, Vero African green monkey kidney cells, mouse BALB/c 3T3 cells, SIRC rabbit cornea cells, and LY mouse fibroblasts developed Fc binding sites. A study of the characteristics of the Fc receptor revealed the following: (1) its appearance required viral protein synthesis, but transcription from the input DNA appeared sufficient to generate the receptor; (2) replication of viral DNA was not necessary; (3) 2-deoxy-D-glucose inhibited the appearance of Fc-binding activity; (4) the receptor had a low turnover and was not rapidly shed from the cell surface; (5) the number of cells showing Fc-binding activity was not related to the cell cycle at the time of infection; (6) the receptor was trypsin-sensitive but neuraminidase-resistant; and (7) following trypsin digestion, cells blocked by cytosine arabinoside regenerated the binding activity. (15 refs)

78-3362 **Electrokinetic Alteration of the Surface of Herpes Simplex Virus Infected Cells.** (Eng) Thompson, C. J. (Dept. Microbiology and Cell Biology, S101 Frear Building, Pennsylvania State Univ., University Park, PA, 16802); Docherty, J. J.; Boltz, R. C.; Gaines, R. A.; Todd, P. *J Gen Virol* 39(3): 449-461; 1978.

Whole-cell electrophoresis and isoelectric focusing were used to investigate changes in the ionic composition of the cell surface induced by herpes simplex virus (HSV). Most of the experiments involved HSV type-1 infection of Wistar rat embryo cells. However, experiments were repeated at various times using HSV type-2 and other cell types to establish that a given observation was not unique to the virus or cell type. Cell electrophoretic mobility (a measurement of negative surface charge density) declined concomitantly with the appearance of newly synthesized infectious virus at 6, 9, and 12 hr postinfection. The max decrement in surface charge density following HSV infection of Wistar rat embryo cells was 19.4%. Cell isoelectric focusing pH increased, indicating that the electrokinetic cell surface became ionically more positive. The decline in surface charge density is consistent with the hypothesis that basic amino groups are being introduced to the cell surface. This hypothesis was further tested by reacting cells with the amino-specific reagent 4-acetamide-4′-isothiocyanostilbene-2,2′-disulfonic acid. Infected cells had 2.4 times as many surface charges affected by the amino-specific reagent as did uninfected control cells. A relationship between these virus-induced amino groups and HSV surface antigens was indicated by the similar kinetics of their appearance and electrophoretic neutralization by HSV antibodies. It is suggested that HSV infection adds positive ionogenic groups to the cell surface. (38 refs)

78-3363 **Interference by Herpes Simplex Virus of Tumorigenesis by Murine Sarcoma Virus.** (Eng) Reilly, C. A. (Div. Biological and Medical Res., Argonne Natl. Lab., Argonne, IL, 60439); Dale, P. J.; Gutzeit, D. L.; Finkel, M. P. *In: Advances in Comparative Leukemia Research 1977. Proceedings on the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 228-229; 1978.

UV-inactivated herpes simplex virus types 1 and 2 (HSV-1 and HSV-2) were injected into newborn CF#1/Anl mice to determine the effect on FBJ virus-induced osteosarcomas. HSV was injected either 24 hr before, 24 hr after, or at the same time as FBJ virus. There were no significant effects on FBJ-induced tumorigenesis when HSV was given at the same time as or 24 hr after FBJ infection. However, when HSV infection preceded FBJ virus infection, a significant reduction in osteosarcomas was noted. After 1 yr, 54% of the mice pretreated with HSV-1 and 83% of those pretreated with HSV-2 developed osteosarcomas compared with 100% of those treated with FBJ only. When mice pretreated with HSV-1 did develop osteosarcomas, the mean time to death was almost doubled and the mean number of tumors/mouse was halved. With HSV-2-pretreated mice that developed osteosarcomas, the mean life-span was almost quadrupled and the number of tumors/mouse was cut by 40%. No specific pathology appeared in mice treated with HSV only. These results indicate that HSV can interfere with FBJ virus tumorigenesis; the mechanism by which this is accomplished is not known. (1 ref)

78-3364 **Cleavage of Epstein-Barr Virus DNA by Restriction Endonucleases EcoRI, HindIII and BamI.** (Eng) Rymo, L. (Dept. Clinical Chemistry, Univ. Gothenberg, Sahlgren's Hosp., S-413 45 Gothenburg, Sweden); Forsblom, S. *Nucleic Acids Res* 5(4): 1387-1402; 1978.

Cleavage of the DNA's of the B95-8 and P3HR-1 strains of Epstein-Barr virus (EBV) by the restriction endonucleases *Eco*RI, *Hin*dIII, and *Bam*I was investigated using a new technique for quantitative evaluation of the fluorescence of ethidium-stained DNA fragments separated on agarose gels. Most B95-8 DNA fragments produced by *Eco*RI and *Hin*dIII cleavage appeared to be present in one copy per DNA molecule. Digestion of *Bam*I yielded a larger number of fragments, including one with a molecular mass of 2.0 megadaltons that was present in 11 copies and localized to a limited part of the DNA molecule. The same sequences were also present in the P3HR-1 DNA, although in a lower molar ratio. P3HR-1 DNA yielded restriction enzyme cleavage patterns suggesting DNA sequence heterogeneity of P3HR-1 virus. No fragment was present in more than about four copies per molecule of P3HR-1 DNA. Comparison of the restriction enzyme cleavage patterns of P3HR-1 and B95-8 DNA revealed a high degree of structural homology emphasized by nucleic acid hybridization experiments with EBV complementary RNA synthesized in vitro. (22 refs)

78-3365 **Detection of the EBV-determined Nuclear Antigen (EBNA) in Burkitt's Lymphoma and Nasopharyngeal Carcinoma Biopsies by the Acid Fixed Nuclear Binding (AFNB) Technique.** (Eng) Luka, J. (Dept. Tumor Biology, Karolinska Institutet, S 104 01 Stockholm 60, Sweden); Klein, G.; Henle, W.; Henle, G. *Cancer Lett* 4(4): 199-205; 1978.

Epstein-Barr virus (EBV)-carrying biopsy specimens of Burkitt's lymphoma (BL) and nasopharyngeal carcinoma (NPC) patients were used to determine whether EBV-associated nuclear antigen (EBNA) can be demonstrated in these tissues by the acid-fixed nuclear binding (AFNB) technique. Extracts of five BL and five NPC specimens gave a brilliant, EBNA-specific fluorescence after binding to acid-fixed chicken RBC. All BL and NPC extracts gave strong positive nuclear fluorescence with anti-EBNA-positive sera, but not with anti-EBNA-negative sera. Similar extracts of three other African tumors that are not known to carry the EBV genome were negative, even though they were derived from EBV-seropositive patients with relatively high anti-EBV viral capsid antigen antibody titers. In tests with BL and NPC-derived material, the anticomplement immunofluorescence reaction was equally strong with both crude tumor extracts and DNA-cellulose-purified extracts, provided the reaction was performed at 4 C. Incubation of the extracts at 37 C led to a more rapid breakdown of the EBNA in the crude material than in the DNA-cellulose concentrated material. These findings indicate that AFNB can be used to detect EBNA in biopsy specimens. (15 refs)

78-3366 **Epstein-Barr Virus-determined Nuclear Antigen in Malignant Epithelial Cells of Nasopharyngeal Carcinoma.** (Eng) Suzuki, T. (First Dept. Pathology, Niigata Univ. Sch. Medicine, 1-Bancho, Asahimachi-dori, Niigata 951, Japan); Katano, A.; Oboshi, S.; Sairenji, T.; Hinuma, Y. *Gann* 69(1): 133-138; 1978.

A test for the presence of Epstein-Barr nuclear antigen (EBNA) in the malignant epithelial cells of a human nasopharyngeal carcinoma was made by first transplanting tumor tissue in nude mice. Tumor tissue was removed from a lymph node metastasis in a 56-yr-old woman and transplanted sc into two nude BALB/c mice. Optical and electron microscopy indicated that the tumors grown in the mice were identical to the one removed from the woman. Tumor cells from the second passage were dispersed in vitro, and EBNA was detected in smears of the malignant epithelial cells. EBNA was not detected, however, in tumor cell imprints made at passage 1, probably because of inadequate preservation. (10 refs)

78-3367 **Detection of Epstein-Barr Virus (EBV) DNA Sequences Using In Situ Hybridization.** (Eng) Moar, M. H. (Dept. Tumor Biology, Karolinska Inst., 10401 Stockholm 60, Sweden); Klein, G. *Biochim Biophys Acta* 519(1): 49-64; 1978.

Epstein-Barr virus complementary RNA (EBV cRNA) hybridization in situ was used to detect EBV DNA sequences under conditions in which the virus DNA is replicating spontaneously and under conditions in which it is induced to do so following superinfection. Optimum conditions for the in situ detection of EBV DNA in single cells were determined. Preliminary experiments using three Burkitt's lymphoma-derived cell lines (the producer P3HR-1 line, the nonproducer Raji line, and the EBV DNA-negative line BJAB) showed that the hybridization is specific and potentially highly sensitive. Therefore, P3HR-1 cells were used in most of the remaining experiments. The most effective fixatives were methanol/acetic acid (3:1) or methanol/acetone (1:2); and NaOH (0.05 M) was far superior to HCl in denaturing the EBV DNA, which has a high (58%) guanosine + cytosine content. Additional optimal conditions were a temperature of 50 C, a cRNA concentration of 3 nanograms/ml, and a hybridization time of 12 hr. Pretreatment of the cells with RNase did not reduce the percentage of labeled cells or the av number of grain counts/cell, but DNase abolished the autoradiographic reaction completely. ^{3}H-DNA was also an effective probe for the detection of specific DNA sequences in single cells. In experiments with producer, nonproducer, and EBV DNA-negative cells, the percentage of cells positive for EBV DNA correlated with the percentage expressing early antigen. It is concluded that under appropriate conditions, EBV DNA sequences can be detected specifically at the single cell level with a high degree of efficiency. (42 refs)

78-3368 **Lymphotropic Herpesviruses in Hodgkin's Disease.** (Eng) Napel, C. (Clinical Immunology Unit, Dept. Medicine, Univ. Groningen, Groningen, Netherlands); Bijker, J.; De Gast, G. C.; Halie, M. R.; Langenhuysen, M. M.; The, T. H. *In: Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds.(New York: Elsevier/North Holland Biomedical Press): 503 pp.; 223-225; 1978.

The lymphocyte reactivity of 24 patients with Hodgkin's disease (HD) to Epstein-Barr virus (EBV) and cytomegalovirus (CMV) was determined and compared with that of age- and sex-matched controls. HD patients showed decreased EBV cellular immunity in association with elevated EBV-viral capsid antigen antibody titers. CMV cellular immunity was also decreased, especially in CMV-early antigen antibody seropositive patients. Lymphocyte reactivity to phytohemagglutinin, concanavalin A, and an antigen cocktail was lower in the patients, but reactivity to pokeweed mitogen was not impaired. In most cases, the general lymphocyte reactivity of the patients was in the normal range. It is suggested that high EBV- and CMV-antibody levels in HD are caused by defective virus specific cellular immunity early in the course of the disease, before disease-associated general depression of lymphocyte function has occurred. (9 refs)

78-3369 **A New Tumour-derived Transforming Strain of Epstein-Barr Virus.** (Eng) Pizzo, P. A. (Infectious Diseases Section, Pediatric Oncology Branch, NCI, Bethesda, MD, 20014); Magrath, I. T.; Chattopadhyay, S. K.; Biggar, R. J.; Gerber, P. *Nature* 272(5654): 629-631; 1978.

A new strain of Epstein-Barr virus (EBV) was isolated from

cell line (AG876) established from the splenic tumor of an
-yr-old Ghanaian boy with Burkitt's lymphoma. Almost all
he cells contain EB nuclear antigen (EBNA), and 5%-20%
nanifest the late viral product, cytoplasmic viral capsid anti-
en (VCA). The AG876 virus has only been propagated in
he cell line derived directly from this splenic tumor. Virus
urified from the AG876 culture medium transformed hu-
nan umbilical cord WBC but failed to induce early antigen
EA) in Raji cells. Purified AG876 DNA banded at a density
f 1.7180 g/cm^3 in a CsCl equilibrium gradient, which is
onsistent with previous analyses of EBV DNA. Association
inetic experiments revealed $\geq$ 90% hybridization of the la-
eled AG876 viral DNA probe with its respective producer
ost cell DNA, as well as with the cellular DNA's from
3HR and B95-8, two other EBV producer cell lines. There
vas virtually 100% homology in the kinetics of hybridization
f AG876 with P3HR1 and B95-8 DNA's, suggesting close
imilarity between the AG876 viral DNA and that of both
3HR and B95-8. AG876 virus seems to be a unique strain
f EBV that is more representative of a wild-type (or putative
tumor virus) strain of EBV than other available strains. (19 refs.)

KCl-solubilized tumor antigens from female C57BL/6J mice bearing methylcholanthrene-induced (0.5 mg, im) fibrosarcomas were isolated and characterized. Material with both a high ($>$300,000 daltons) and low ($<$30,000 daltons) mol wt inhibited ^{3}H-thymidine incorporation by lymphoid cells taken from tumor-bearing animals. When the inhibitor was removed, however, the remaining material stimulated proliferation in these lymphoid cells over a wide range of mol wts ($<$30,000 to $>$100,000 daltons). (18 refs)

A RBC oncodevelopmental antigen was serologically dissec
ed into eight antigenic determinants. Rabbit antisera pr
pared against RBC from 1-day-old chicks and adsorbed wi
RBC from adult chickens of identical strains were used
detect the presence of antigenic determinants on RBC of se
eral avian species. On the basis of differential adsorptions ar
hemagglutination reactions, eight different antigenic determ
nants were recognized. The expression of these determinan
was compared on RBC of differently aged birds. There w
a loss (or addition) of antigenic determinants with aging. Th
RBC membrane antigens were of phylogenetic interest b
cause of their differential expression among avian specie
RBC from adult and embryonic turkeys expressed only ant
genic determinant 1, whereas RBC from chicken, pheasan
and Japanese quail embryos, which all belong to the sam
family, expressed 1-8, 1-5, and 1-4 antigenic determinant
respectively. Differential expression of the antigenic determ
nants with aging and species of bird should permit studie
of the expression of antigenic determinants with developme
and malignancy. (14 refs)

8-3379 Effect of the Prolonged Immunization with Tumor-unrelated Antigen on the Tumor Growth. Eng) Targowski, S. P. (Dept. Microbiology, State Univ. New York at Buffalo, Sch. Medicine, Buffalo, NY, 14214); Albini, B.; Milgrom, F. *Proc Soc Exp Biol Med* 157(3): 511-516; 978.

The growth of a methylcholanthrene-induced sarcoma, MCSa-22, in C3H/HeHa mice was investigated after the mice had been immunized for 4-5 mo with bovine serum albumin (BSA) or ovalbumin (OA). A dose of 0.2 mg BSA or OA in 0.2 ml saline was administered iv or ip, respectively. The umor was injected when deposits of immune complexes could be demonstrated in the kidneys. BSA-immunized mice were given 10^4, 10^3, or 10^2 tumor cells. All immunized mice developed tumors within 8-17 days; similar findings were obained in unimmunized controls, except only 6/10 receiving he lowest dose developed tumors, 3 within 17 days, 3 within 43 days. In all groups, tumors from immunized mice weighed significantly more than tumors from controls. OA-mmunized mice were given 10^5, 10^4, or 10^3 cells. Tumors were detected in most immunized and control mice by day 12; however, only 6/12 controls given the lowest dose developed tumors. Tumor wt in mice given the highest OA dose was significantly greater than that in controls. Tumors from BSA- and OA-immunized mice showed no difference in the adsorption of sensitized sheep RBC; sera from the immunized mice markedly inhibited hemadsorption, but sera from normal mice did not. The distribution of immune complexes in mmunized and control mice is outlined. (25 refs)

78-3386 Expression of an Antigen Associated with Acute Lymphoblastic Leukemia in Human Leukemia-Lymphoma Cell Lines. (Eng) Minowada, J. (Dept. Immunology, Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263); Janossy, G.; Greaves, M. F.; Tsubota, T.; Srivastava, B. I.; Morikawa, S.; Tatsumi, E. *J Natl Cancer Inst* 60(6): 1269-1277; 1978.

Thirty human hematopoietic cell lines were studied for the presence of the cell-surface antigen (cALL antigen) associated with the non-T-cell, non-B-cell form of acute lymphoblastic leukemia (ALL). Nine of 20 proven leukemia-lymphoma cell lines were positive for cALL antigen, but all 10 normal Epstein-Barr virus-positive, B-lymphoblastoid cell lines were negative. On the basis of cell markers, the 9 cALL antigen-positive cell lines included 2 non-T-, non-B-cell ALL's, 1 lymphoid-type blast crisis of chronic myelocytic leukemia, 4/6 T-cell leukemia-lymphomas, and 2/10 B-cell lymphomas. Cross-absorption studies established the complete antigenic cross-reactivity of the cALL antigen on these various cell lines and fresh cALL antigen-positive leukemia cells. Although ALL's with a T-cell phenotype (T-cell ALL's) were previously shown to lack the cALL antigen, the antigen was definitely, although weakly, expressed on 7/89 uncultured T-cell leukemias. Serial studies of the cell cultures demonstrated stable expression of the cALL antigen. These results are interpreted in terms of a pluripotential stem cell and/or lymphoid precursor cell association of the cALL antigen. (58 refs)

78-3389 **The Effect of Interferon on the Early Functions of Simian Virus 40.** (Eng) Mozes, L. W. (Dept. Pathology, New York Univ. Sch. Medicine, New York, NY, 10016); Defendi, V. *Virology* 85(1): 315-318; 1978.

The ability of interferon (IF) to interfere with the penetration and uncoating of simian virus 40 (SV40) was studied by monitoring the inhibition of SV40-induced tumor antigen (T Ag) in permissive TC7 monkey cells and nonpermissive mouse embryo fibroblasts. Addition of IF to cells previously transformed by SV40 had no effect on T Ag production. However, pretreatment of cells with homologous IF 20 hr prior to SV40 injection resulted in a dose-dependent decrease in the proportion of T Ag-positive cells at 48 hr postinfection. IF addition at increasingly later times after SV40 injection resulted in a progressive reduction in T Ag-positive cells; the sensitivity to inhibition by IF was lost by 12 hr after infection. Penetration and uncoating of SV40 were ruled out as the major site of IF action, since the induction of T Ag by infectious DNA extracted from SV40 virions was also sensitive to IF treatment. Furthermore, addition of IF to cells did not result in resistance to viral infection until several hours had elapsed. These findings suggest that the inhibitory effect of IF is primarily at a step between SV40 uncoating and integration of viral DNA into the host cell genome. (16 refs)

78-3394 **Cross-reactivities of Ethylnitrosourea-induced Neurogenic Rat Tumors Studied by In Vitro Assays for Cell-mediated Immunity.** (Eng) Oda, Y. (Dept. Neurosurgery, Kyoto Univ. Medical Sch., Shogoin-Kawaracho 54, Sakyo, Kyoto 606, Japan); Handa, H.; Kieler, J. *Eur J Cancer* 14(5): 491-499; 1978.

The cross-reactivities of neurogenic tumors induced transplacentally in Wistar rats by ethylnitrosourea (ENU; 60 mg/kg ip to the pregnant mother) were studied by various in vitro tests for cell-mediated immunity. Migration-inhibition tests (MIT) were performed using neurogenic tumor extracts, a spontaneous mammary carcinoma, and various normal adult and fetal tissues. An indirect ^{51}Cr-release assay and an indirect DNA-inhibition test were performed with culture supernatants from mixed cultures of neurogenic tumor cells and sensitized or nonsensitized lymphoid cells. All three assays revealed tumor-associated antigens with cross-reactions between various neurogenic tumors. Cross-reactions were also demonstrated by MIT between neurogenic tumors and fetal tissues. A peripheral neurinoma cross-reacted with adult brain, and a trigeminal nerve neurinoma cross-reacted with the spontaneous mammary carcinoma. None of the neurogenic tumors cross-reacted with adult liver. Thus, ENU-induced neurogenic tumors share one or several common antigens that are not tumor-specific. The reactivity of lymphoid cells from tumor-bearing rats was considerably weaker than that of lymphoid cells from hyperimmunized rats. The reactivity of lymphoid cells from the thymus and lymph nodes was considerably stronger than that of splenocytes. (24 refs)

78-3395 **Immune Responses to Weakly Immunogenic Virally Induced Tumors. 1. Overcoming Low Responsiveness by Priming Mice with a Syngeneic In Vitro Tumor Line or Allogeneic Cross-reactive Tumor.** (Eng) Galili, N. (Lautenberg Center General and Tumor Immunology, Hebrew Univ.-Hadassah Medical Sch., Jerusalem, Israel); Devens, B.; Naor, D.; Becker, S.; Klein, E. *Eur J Immunol* 8(1): 17-22; 1978.

Attempts were made to overcome the immunologic unresponsiveness of A strain mice to YAC tumor, a syngeneic Moloney virus-induced lymphoma, and of C57BL/6 mice to RBL5 tumor, a Rauscher virus-induced lymphoma. Significant cytotoxic responses could be generated against the YAC tumor by immunizing A mice with YAC-1, a tissue culture line of YAC, and culturing the primed spleen cells from these immunized mice for 6 days. Spleen cells from A mice inoculated with tumor cells from the in vivo tumor line failed to generate a syngeneic cytotoxic response. Spleen cells from A mice that were inoculated with the cross-reactive allogeneic tumor RBL5 could generate significant cytotoxic responses to the syngeneic tumors YAC and YAC-1. Similarly, spleen cells from C57BL/6 mice inoculated with the cross-reactive allogeneic tumor YAC-1 could generate a significant cytotoxic response to the syngeneic tumor RBL5. RBL5, in contrast to the YAC tumor, was immunogenic in its in vivo form, and subsequent culturing did not improve its immunogenicity. Thus, cross-reactive allogeneic tumors can stimulate syngeneic cytotoxicity. (32 refs)

78-3397 **Is Protein Synthesis Necessary for the Commitment of Lymphocyte Transformation?** (Eng) Milner, J. (Dept. Biochemistry, Univ. Cambridge, Cambridge, England). *Nature* 272(5654): 628-629; 1978.

Studies were conducted to determine whether protein synthesis is necessary for the initial commitment of cells into the mitotic cell cycle following concanavalin A (Con A) stimulation of resting lymphocytes. Mitogenesis was measured by the incorporation of ^{3}H-thymidine into cellular DNA during the period 48-50.5 hr after exposure to Con A. Anisomycin, an inhibitor of protein synthesis, had no effect on the transformation of spleen cells from BALB/c mice when added to the culture medium at 3.8 nM; 10 nM anisomycin reduced transformation considerably, and at 38 nM it completely blocked Con A-induced transformation. The inhibitory effect of anisomycin could be reversed by replacing the medium containing anisomycin plus Con A with fresh medium plus Con A or with fresh medium only. The ability of lymphocytes to transform following removal of both anisomycin and Con A was similar to that observed when only the anisomycin was removed. The Con A-induced transformation of splenic lymphocytes is thus sensitive to very low concentrations of anisomycin, which block the increase in protein synthesis in con A-stimulated cells, as determined by measuring the incorporation of ^{35}S-methionine into proteins. The observation that lymphocytes become independent of extracellular Con A for transformation (after removal of both anisomycin and Con A) implies that commitment of lymphocytes to enter the mitotic cycle may be independent of protein synthesis. (8 refs)

78-3398 **Immunological Reactivity of BALB/c Mice During Moloney Sarcoma Virus Infection.** (Eng) Marshall, G. D. (Dept. Biology, Texas A&M Univ., College Station, TX); Foster, B. G. *FEMS Microbiol Lett* 3(1): 43-46; 1978.

Daily nonspecific immune responses were studied in BALB/c mice infected with Moloney murine sarcoma virus (MSV: 0.1 ml of a stock soln diluted to 0.62 log focus-forming unit/ml, im). Lymphocyte responses to phytohemagglutinin-p (PHA-P) indicated the existence of a generalized immunocompetence until day 12, when the MSV-induced tumors reached their max size. After declining on days 12-15, the PHA-P responses returned to normal on day 21, concomitant with tumor regression. Responses to concanavalin A increased exponentially after day 13 and remained elevated until day 7. A significant decline in the response to pokeweed mitogen on day 13 was repaired within 1 day. Mixed lymphocyte reaction responses paralleled the PHA-P responses, indicating a decrease in cell-mediated immunity on days 14-15. The results are discussed in terms of the relative maturation steps from uncommitted lymphocytes to immunologically mature T cells. (19 refs)

78-3402 **Abnormalities of Lymphocyte Transformations in Women with Condylomata Acuminata.** (Eng) Seski, J. C. (M.D. Anderson Hosp. and Tumor Inst., Houston, TX, 77025); Reinhalter, E. R.; Silva, J. *Obstet Gynecol* 51(2): 188-192; 1978.

The antigen-induced lymphocyte transformation responses of 16 women with recalcitrant condylomata acuminata were compared with those of 24 matched controls to determine if the growths are a reflection of an underlying defect in cell-mediated immunity. Lymphocyte transformation responses to phytohemagglutinin, concanavalin A, and pokeweed mitogen were significantly lower for the patients than for the controls. There was no significant difference between the two groups in lymphocyte transformation in Candida or streptokinase-streptodornase antigens. Approx 33% of each group took oral contraceptives; of these women, the mitogenic responses of the patients remained lower than those of the control group. In the patient group, 2 with diabetes mellitus, 1 with lupus erythematosis, and 1 with intraepithelial carcinoma of the vulva, vagina, and cervix had the lowest mitogenic responses. It is suggested that a refractory course of condylomata acuminatum in some women may reflect an underlying immunosuppressed state. (21 refs)

78-3403 **Allograft Cytotoxicity Co-Operation Between Alloimmune T Cells and Macrophages.** (Eng) Jones, B. (Dept. Immunology, Arthur Stanley House, Middlesex Hosp. Medical Sch., 40-50 Tottenham St., London W1P 9PG, England); Jones, T. C. *Immunology* 34(2): 247-255; 1978.

The ability of spleen cells from C57BL/10 (H-2b) mice to cooperate directly with normal macrophages in the destruction of target cells was investigated using a micro-culture system. Mice were immunized by ip injection of 2.5 x 10^7 P815Y (H-2d) cells, and 7-12 days later, spleen cells from these mice cooperated with an adherent component of nonimmune starch induced peritoneal cells in the cytostasis of P815Y target cells; no activity was expressed against an EL4 (H-2b) lymphoma. Although significant values for synergy could be obtained using the ^{125}I-iododeoxyuridine-incorporation assay to measure cytostasis, normal peritoneal cells were incapable of cooperating with T cells in cytolysis, as measured by ^{51}Cr release from prelabeled target cells. Initially, the synergistic interaction was immunologically specific, but nonspecific activity could be induced by challenge with specific antigen. Furthermore, both the direct specific synergistic reaction and the indirect nonspecific reaction required T cell function. (12 refs)

78-3404 **The Immunodepressive Effect of Friend Virus. IV. Effects on Spleen B Lymphocytes.** (Eng) Dracott, B. N. (Immunology Div., Dept. Pathology, Royal Coll. Surgeons England, Tennis Court Road, Cambridge CB2 1QP, England); Wedderburn, N.; Doenhoff, M. J. *Immunology* 34(4): 679-687; 1978.

Splenic immune responses having varying dependence on accessory cell cooperation were studied after the infection of mice with Friend virus (FV). Infection had no effect on cell proliferation or antibody production in cultures stimulated with *Escherichia coli* lipopolysaccharide. The in vivo response to type III pneumococcal polysaccharide was depressed only moderately. The response to sheep RBC was depressed severely both in vivo and in vitro. However, the latter was greatly reduced by costimulation of the cultures with *Escherichia coli* lipopolysaccharide. The depletion of potential suppressor lymphocyte populations by irradiation or adult thymectomy did not ameliorate the depression of responses to sheep RBC or pneumococcal polysaccharide as a result of FV infection. However, when mice were subjected to thymectomy, irradiation, and marrow restoration, FV infection had no significant effect on the responses of T-lymphocyte-depleted mice. It is suggested that precursor B-lymphocyte depletion is not responsible for immune depression by FV, at least after short infection intervals. It is also suggested that FV acts on inductive rather than effector processes and that the greater the resulting depression, the greater the dependence of the latter on cooperation, especially by T lymphocytes. Conversely, precursor B-lymphocyte subpopulations that respond in the absence of cooperation may be affected less or not at all by FV. (44 refs)

78-3412 **Prevalence of Neutralizing Antibodies Against Adenoviruses at Lucknow.** (Eng) Mathur, A. (Upgraded Dept. Pathology and Bacteriology, K.G. Medical Coll., Lucknow-226003, India); Singh, G.; Singh, U. K.; Mehrotra, R. M.; Chaturvedi, U. C. *Indian J Med Res* 67: 19-26; 1978.

Blood samples from 400 healthy subjects of Lucknow, India were analyzed for the presence of antibodies (ab) to adenovirus (Ad) types 2, 7, and 8. Ab against one or more of the Ad's were found in 103 sera, 14 of which contained ab to more than one type of Ad. Most of the sera were positive for Ad2 (55 samples), followed by Ad7 (40) and Ad8 (23). The highest incidence of Ab was seen in children < 10 yr of age. (19 refs)

Epidemiology and Microbiology, Moscow, USSR); Chernousova, L. N.; Shevliagin, V. Ia.; Morgunova, T. D. *Dokl Akad Nauk SSSR* 239(5): 1233-1234; 1978.

To test whether elimination of the specific blocking factor (the factor that defends tumor cells from T lymphocytes, or killer cells) would result in regression of tumor growth, BALB/c mice inoculated with Rauscher virus were immunized with antiserum (MAAS) against aggregated immunoglobulins. MAAS antiserum was obtained from BALB/c mice immunized with isologous immunoglobulins that had been heated at 63 C for 20 min. The antiserum (0.1 ml) was injected ip daily for the first 4 days, every other day for the next 22 days. Mice in the control group received injections of normal serum from BALB/c mice. Although all mice developed leukemia, the lifespan of mice treated with MAAS antiserum was 46.5 days, compared with 30.9 days in the controls. (11 refs)

78-3414 **Humoral Antibodies in Patients with Leukemia and Infectious Mononucleosis.** (Rus) Vyadro, M. M. (Lab. Experimental Tumor Therapy, P. A. Gertsen Scientific Res. Cancer Inst., Moscow, USSR); Bergolts, V. M.; Korzhenkova, M. P. *Pediatriia* (8): 47-50; 1977.

To determine whether the serum from patients with infectious mononucleosis (IM) contains cytotoxic anti-leukemic antibodies, 20 serum specimens from 17 children with IM were tested in a direct cytotoxicity assay with cell targets from 10 leukemic patients (6 had acute lymphoblastic leukemia, 3 chronic lymphoblastic leukemia, and 1 chronic myeloid leukemia). Cytotoxic antileukemic antibodies were absent in all 20 sera, but some sera contained noncytotoxic 7S antibodies, which could be detected in an indirect cytotoxicity assay. Preincubation of the serum with leukemic cell targets enhanced the cytotoxic effect of anti-7S serum. (12 refs.)

78-3417 **Human Monocyte-induced Tumor Cell Cytotoxicity.** (Eng) Rinehart, J. J. (Hematology Section, Veterans Admin. Hosp., 54th St. and 48th Ave., Minneapolis, MN, 55417); Lange, P.; Gormus, B. J.; Kaplan, M. E. *Blood* 52(1): 211-220; 1978.

Monocyte-induced tumor cell cytotoxicity (MITC) was examined in vitro using monocytes obtained from normal human donors and four human tumor cell lines: CAK-5, a renal cell carcinoma; T-24, a transitional bladder cell carcinoma; Malme-3M, a melanoma; and SK-MES-1, an epidermoid lung carcinoma. Cocultivation of monocytes and tumor cells, as observed by light microscopy, resulted in marked monocyte-tumor cell interaction and a reduction in tumor cell number. Excellent correlation was obtained between the percentage of cytotoxicity determined by direct cell counts and by ^{3}H-thymidine incorporation. MITC increased with monocyte/tumor cell ratios in three tumor cell lines but not in SK-MES-1. Monocytes were significantly more cytotoxic for Malme-3M than for the other three lines (80% cytotoxicity at a monocyte/target cell ratio of 32:1 vs 38%-50% for the other three lines). MITC was not due to a soluble cytotoxin, serum complement, or putative "natural" tumor cell antibodies, and it was not a nonspecific effect of cell-cell interaction. MITC was not mediated by reduction in space available for tumor cell adherence and it was not an artifact due to media depletion. These results suggest that human monocytes have a cytotoxic potential against tumor cells in vivo. (21 refs)

78-3423 **Derepression of Nuclear Template Restrictions for DNA Synthesis by the Immunostimulator Pyran Copolymer.** (Eng) Mohr, S. J. (Div. Urology, Univ. Colorado Medical Center, Denver, CO, 80220); Massicot, J. G.; Chirigos, M. A. *Cancer Res* 38(6): 1610-1616; 1978.

The effect of the immunostimulator pyran copolymer on in vitro DNA synthesis was investigated using mouse liver nuclei. Pyran interacted with the repressed genome of isolated murine liver nuclei and allowed DNA synthesis to take place. This interaction occurred immediately and was influenced by the magnesium concentration, pyran concentration, and mol wt of the pyran. Furthermore, pyran could reverse the histone-induced inhibition of a pure poly(deoxyadenylate-deox-

thymidylate) template primer for DNA synthesis. Parallel
esults were obtained with both intact nuclei and nuclei that
ad undergone disruption, indicating that no interaction with
ie nuclear membrane was involved in these results. In addi-
on, morphological swelling of the nuclei was seen in the
resence of pyran concentrations that were maximally
imulatory to DNA synthesis. Pyran, therefore, is able to
elease the DNA template of murine liver nuclei from restric-
ons that normally would prevent them from serving as a
seful template for DNA synthesis. It is not known whether
ie ability of pyran to derepress the nuclear DNA template
related to its action in potentiation of vaccine, macrophage
imulation, and interferon induction. (33 refs)

The effects of immunosuppressive PB815X mastocytoma cells and cell-free extracts of this tumor on the appearance of IgM vs IgG antibody-producing cells were examined in DBA/2 mice after primary or secondary immunization. Immunologic impairment was noted in mice bearing PB815X tumors and in mice inoculated with cell-free extracts and/or ascites fluid from the tumor-bearing animals. The 19S IgM antibody response to sheep RBC was preferentially affected. Although there were 60%-80% fewer IgM plaque-forming cells (PFC) in mice given a primary injection with sheep RBC, there was only a slight effect on the appearance of indirect 7S IgG PFC. Mice primed with sheep RBC and then implanted with mastocytoma cells showed a marked impairment of the secondary IgM response but no depression of the IgG response. Injection of cell-free ascites fluid from tumor-bearing mice into normal recipient mice before primary or secondary immunization with sheep RBC resulted in marked depression of the IgM response only. These results suggest that PB815X cells preferentially affect the immunocytes producing IgM hemolytic antibody. (10 refs)

78-3436 **Macrophages and Resistance To Tumours. I. Inhibition of Delayed-Type Hypersensitivity Reactions by Tumour Cells and by Soluble Products Affecting Macrophages.** (Eng) Nelson, M. (Kolling Inst. Medical Res., Royal North Shore Hosp., St. Leonards NSW 2065, Australia); Nelson, D. S. *Immunology* 34(2): 277-290; 1978.

Tumor cell inhibition of delayed-type hypersensitivity (DTH) reactions was examined. A/J mice were footpad-inoculated with mixtures of sheep RBC to which they had developed DTH and syngeneic 3-methylcholanthrene-induced fibrosarcoma cells. DTH reactions were associated with a depression of subsequent tumor growth compared with that in control animals. The degree of depression was proportional to the intensity of the reactions. Conversely, the presence of fibrosarcoma cells was associated with depression of DTH reactions. Serum-free culture supernatants of various mouse, human, and rat tumors depressed DTH reactions in mice, the depressive activity being apparent even at dilutions > 1:100. Supernatants from cultures of nonmalignant cells had little or no depressive activity. Protein synthesis, but not DNA synthesis, was required for the production of the responsible factors. In vitro, the active supernatants markedly inhibited macrophage migration, either spontaneously or in response to a chemotactic factor, but they had much less effect on mitogen-stimulated or unstimulated lymphocyte cultures. The activity was decreased or lost after treatment with proteolytic enzymes, ribonuclease, neuraminidiase, or hyaluronidase. Membrane ultrafiltration showed that the activity was associated with materials of mol wt > 1,000. However, materials of mol wt > 10,000 and < 10,000 had different in vivo effects, with the larger factors being more depressive of the later phases of the reaction and the smaller factors being more depressive of the earlier. Injection of concentrated supernatants from the tumors together with fibrosarcoma cells led to more rapid initial tumor growth. (36 refs)

78-3437 **Immunity to Transplantable Carcinogen-induced Fibrosarcomas in B2/B2 Chickens. III. Tumor Growth Inhibition by Local Delayed Hypersensitivity Reactions to Unrelated Antigens.** (Eng) Palladino, M. A. (Dept. Pathology, New York Univ. Sch. Medicine, 550 First Ave., New York, NY, 10016); Thorbecke, G. J. *Eur J Immunol* 8(4): 257-262; 1978.

In SC chickens, the growth of transplantable fibrosarcomas (SCFS), which were derived from 7,12-dimethylbenz(a)anthracene-induced primary tumors, was suppressed by delayed hypersensitivity (DH) reactions to human immunoglobulin (Ig), *Corynebacterium parvum*, or allogeneic cells at the site of tumor cell injection. Spleen cells of SC chickens sensitized to human Ig or *C. parvum* suppressed SCFS growth only when injected simultaneously with the sensitizing antigen. This suppression did not occur in irradiated recipients. SCFS I cells injected into wattles of tumor-immune chickens provoked a local DH reaction. Spleen cells from donors sensitized to SCFS I adoptively transferred immunity to both SCFS I and SCFS II when cells of the two tumors were mixed together before injection, but not when SCFS II cells were injected alone. Tumor-specific and non-tumor-specific DH may be essential for the local suppression of fibrosarcoma growth in chickens. (31 refs)

78-3438 **Natural Killer Cells May Be the Only Cells in Normal Mouse Lymphoid Cell Populations Endowed with Cytolytic Ability for Antibody-coated Tumour Target cells.** (Eng) Ojo, E. (Dept. Immunology, Uppsala Univ. Biomedical Centre, Box 582, Uppsala, S-751 23, Sweden); Wigzell, H. *Scand J Immunol* 7(4): 297-306; 1978.

Normal mouse lymphoid cells were analyzed for their ability to act as natural killer (NK) cells against an NK-sensitive tumor target (YAC), to act as effector cells against IgG-coated P815 cells, and to function as effector cells against IgG-coated chicken RBC. NK activity and antibody-dependent cell cytotoxicity (ADCC) against IgG-coated P815 cells were found to vary in parallel with respect to the age, organ source, and genotype of the effector cells. On the other hand, ADCC against chicken RBC was largely performed by effector cells distinct from those functioning as NK cells or in ADCC against P815 cells. Preincubation of the cells at 37 C for 4 hr decreased the lytic efficiency of ADCC anti-P815 and NK activity significantly, indicating that both were temperature-sensitive, in contrast to ADCC against chicken RBC. Likewise, ip inoculation of mice with *Corynebacterium parvum* reduced ADCC against chicken RBC, but it increased ADCC against P815 and NK activity. Blocking experiments using 'cold' inhibitor cells in cytolytic assays indicated that NK cells and effector cells against IgG-coated P815 cells were the same. It is thus concluded that NK cells in the mouse also have the ability to express killer cell activity against IgG-coated tumor target cells; NK cells may be the only cell type in the mouse equipped with cytolytic potential for antibody-coated murine nucleated cells. (32 refs)

78-3439 Possible Involvement of Natural Killer Cells in Bone Marrow Graft Rejection. (Eng) Lotzova, E. (Dept. Developmental Therapeutics, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Savary, C. A. *Biomedicine [Express]* 27(9/10): 341-344; 1977.

The similarities between natural killer (NK) cells and hematopoietic resistance effector (HR-E) cells were investigated. Young mice did not express NK or HR-E cells when challenged with parental bone marrow grafts; adult mice were good responders to both types of cells. A dose of 1,100 R whole-body irradiation given 24 hr before in vitro cytotoxicity assays did not abrogate or decrease NK-cell cytotoxicity; HR-E cells were previously shown to be radioresistant. Both populations could be inhibited by cyclophosphamide, silica, carrageenan, and *Corynebacterium parvum*. Mice tolerant to bone marrow grafts and therefore accepting parental marrow transplants showed decreased NK-cell reactivities. These findings suggest, but do not prove, that NK and HR-E cells represent the same population. (29 refs)

78-3440 Natural Killing in Immunodeficient Patients. (Eng) Koren, H. S. (Div. Immunology, Duke Univ. Medical Center, Durham, NC, 27710); Amos, D. B.; Buckley, R. H. *J Immunol* 120(3): 796-799; 1978.

To identify the effector cell for natural killing (NK), NK capacity was evaluated in the peripheral blood mononuclear cells from 14 patients with well-defined primary immunodeficiency (ID) disorders, as these disorders have distinct lymphocyte subpopulation membrane receptor and/or functional abnormalities. In addition, the antibody-dependent cell-mediated cytotoxicity (ADCC) of these cells against antibody-coated RBC and lymphoid or tumor targets was assayed. The patients comprised 5 with X-linked agammaglobulinemia (Xa γ), 6 with common variable agammaglobulinemia (CVA γ), 2 with severe combined ID (SCID), and 1 with ID with hyper-IgM (HypM). NK activity was normal but ADCC against lymphocyte targets was grossly impaired in the HypM and XAγ patients. This selective inability to lyse antibody-coated nonerythroid target cells suggests that (1) two separate subpopulations of effector cells may exist for the two types of killing, (2) one effector cell may exist for both systems, but the effector functions are mediated by two distinct cell-surface recognition structures, or (3) one effector cell exists for both systems but ADCC is more susceptible than NK to abnormalities affecting lymphoid cell function. Cells from the CVAγ patients had demonstrable NK and ADCC activity. The degree of reactivity among these patients varied widely, and it probably reflects the heterogeneous nature of the ID in this group. The only ID state in which lymphocyte NK activity was found to be lacking was SCID. SCID patients showed no ADCC against nonerythroid targets, but they showed normal ADCC against erythroid targets. It is suggested that monocytes and K lymphocytes are capable of mediating ADCC against erythroid targets but that only K lymphocytes can lyse antibody-coated nonerythroid targets. The fact that NK is lacking in the most severe form of ID indicates that NK may be among the more primitive of the host-defense and surveillance mechanisms. (23 refs)

78-3445 Unique and Common Tumor-specific Transplantation Antigens of Chemically Induced Mouse Sarcomas. (Eng) Hellstrom, K. E. (Div. Tumor Immunology, Fred Hutchinson Cancer Res. Center, Seattle, WA); Hellstrom, I.; Brown, J. P. *Int J Cancer* 21(3): 317-322; 1978.

Nine transplantable lines of sarcomas induced in female BALB/c mice by hind leg injection of 0.1 mg 3-methylcholanthrene (3-MC) were tested for their ability to induce transplantation immunity against themselves and against other syngeneic 3-MC induced sarcomas. The mice were immunized by sc injection of 5 x 10^7 x-irradiated tumor cells. Each of the nine tumor lines could induce a stronger tumor-specific transplantation resistance against itself than against other tumors. However, there was also a weak cross-reaction between tumors in the transplantation test, indicative of common tumor-specific transplantation antigens (TSTA). Cross-reactions were seen significantly more often when the immunizing tumor expressed murine leukemia virus (MuLV) antigens, and this was irrespective of the MuLV expression of the challenge tumor. Thus, not only unique, but also common TSTA were found in these lines. (19 refs)

78-3457 **Serum Factors Modulating Host Immunity to SV40 Tumor Cells.** (Eng) Lausch, R. N. (Dept. Microbiology, Milton S. Hershey Medical Center, Pennsylvania State Univ. Coll. Medicine, Hershey, PA, 17033); Prather, S. O. *Fed Proc* 37(7): 2095-2096; 1978.

The immune response of LSH hamsters to isografts of simian virus 40 (SV40)-transformed tumor cells (PARA-7) was investigated. When spleen cells from tumor-bearing animals were tested immediately, they were not cytotoxic to PARA-7 target cells, but they became cytotoxic when they were incubated in vitro overnight. Spleen cells from SV40-sensitized hosts or from animals whose tumor had been surgically removed, were active on direct testing. These findings suggest that the tumor cells released a substance that could inhibit the activity of sensitized spleen cells and that this phenomenon could be reversed. Study of the serum factors modulating host tumor immunity indicated that progressive growth of PARA-7 transplants was accompanied by a demise of serum antibody-dependent cell cytotoxicity (ADCC), an increase in serum blocking, and a loss of spleen cell cytotoxicity. Events occurring during incubation that resulted in reversal of tumor-mediated suppression of cellular cytotoxicity were examined next. During overnight incubation of unreactive spleen cells, a substance was released into the medium that could block cell-mediated immunity. This medium could not mediate ADCC. However, medium overlying effector cells active on direct testing had ADCC but no blocking activity. Antigen extracted from PARA-7 tumor cells and admixed with sensitized effector cells specifically blocked cellular cytotoxicity. Incubation of antigen with serum or medium mediating ADCC resulted in neutralization of such activity and concomitant formation of a factor whose blocking properties in the microcytotoxicity assay were similar to that of tumor bearer serum. Antigen by itself did not block at the level of the target cell. (7 refs)

78-3458 **Inhibitory Effect of BCG Vaccine on Specific Antitumor Immunity of Syrian Hamsters.** (Rus) Agibalova, L. V. (Cancer Res. Center, Moscow, USSR). *Vestn Akad Med Nauk SSSR* (2): 42-46; 1978.

The effect of 'wet' and lyophilized BCG vaccine on nduced specific antitumor immunity was studied in Syrian hamsters. The animals were immunized with a single ip injection of simian virus 40 (SV40: 1 ml) or of 10^5-10^7 irradiated (12,000 rads) tumor cells (SV40-nduced sarcoma ICV or spontaneous hepatoma Gt-11B). Antitumor immunity was assessed by in vivo transplantation tests. Sc injection of 'wet' BCG vaccine, at doses ranging from 0.25 to 1.0 mg per 0.2 ml, reduced specific resistance of immunized hamsters to SV40. This did not occur with the lyophilized form. In experiments with irradiated tumor cells, again only the 'wet' BCG vaccine decreased the antitumor resistance of inoculated hamsters both to sarcoma ICV and hepatocellular carcinoma. (18 refs)

78-3464 **Influence of Serial Transplantation on the Immunological-Clinical Correlates of BALB/cfC3H Mouse Mammary Tumors.** (Eng) Hager, J. C. (Dept. Medicine, Roger Williams General Hosp., 825 Chalkstone Ave., Providence, RI); Miller, F. R.; Heppner, G. H. *Cancer Res* 38(8): 2492-2500; 1978.

An attempt was made to characterize clinically a set of serially transplanted BALB/cfC3H mammary tumors in terms of their latency periods, growth rates, invasiveness, and capacity to metastasize and, simultaneously, to test their ability to induce cell-mediated immunity, serum-blocking factors, and lymphocyte-dependent antibody. Sixty tumors representing up to 10 passage generations of 7 spontaneously arising mammary adenocarcinomas growing sc in BALB/cfC3H mice were used. No significant correlation was observed between any of the clinical characteristics. Cell mediated immunity was associated with slower growth rates and the presence of metastases. Serum-blocking factors were detected more frequently in mice exposed to tumors with shorter latency periods and faster growth rates. They were also detected more frequently with nonmetastatic implants than with tumors capable of metastasizing to the lungs or visceral organs. Lymphocyte-dependent antibody was associated with slow-growing and noninvasive tumors. Thus, different types of immune reactivity are associated with different aspects of clinical behavior. The data were further analyzed to assess the influence of serial transplantation on the behavioral and immunological characteristics of the seven mammary tumor populations. Although the results were illustrative of the principles of progression described previously, there was a marked fluctuation of all seven characteristics from generation to generation. This fluctuation is interpreted in the context of the existence within one tumor cell population of distinct subpopulations of tumor cells heterogeneous with regard to growth and malignant potential. ncultured cells of the near-diploid mouse plasmacytoma
IOPC-31C, which contains 44 chromosomes, were studied
sing chromosome-banding techniques. An unexpected find-
g was the absence of the two markers, derived from a recip-
ocal translocation between chromosomes 12 and 15, that
ere consistently present in three uncultured near-tetraploid
yelomas and also in a diploid mouse myeloma. In the
ear-diploid mouse plasmacytoma, chromosome 15 par-
cipated in a reciprocal translocation with chromosome 6,
orming two different markers (m3 and m5) unique to this
mor. However, the location of the breakpoint in chromo-
ome 15 was the same as that required for the formation of
e reciprocal translocation between chromosomes 12 and 15
 the other tumors. This common breakpoint is likely to be
nportant in the development of mouse plasmacytomas. It
suggested that the relationship of the breakpoint in
hromosome 15 to plasmacytoma in the mouse may be analo-
ous to the relationship between the Philadelphia chromo-
ome and chronic myelogenous leukemia in man. (26 refs)

8-3468 **Chromosomal Aberrations and Morphological Transformation of Hamster Embryonic Cells
nduced by L-Tryptophan Pyrolyzate In Vitro.** (Eng) Tsuda,
I. (Biological Res. Center, Japan Tobacco and Salt Public
orp., Hatano, Kanagawa-ken, 257, Japan); Kato, K.; Mat-
umoto, T.; Yoshida, D.; Mizusaki, S. *Mutat Res* 49(1): 145-
48; 1978.

he ability of the pyrolyzate of L-tryptophan (TP) to induce
hromosomal aberrations and morphological transformation
 Syrian hamster embryo cells was determined. Primary or
econdary cultures were exposed for 24 hr to TP concentra-
ions of 1-100 μg/ml and assayed for chromosomal aberra-
ions. Because of cytotoxicity, metaphase cells were not de-
ected at TP concentrations > 75 μg/ml. At 30 and
0 μg/ml, a significant increase in aberrations was
bserved, with breaks and exchanges being the most
requent changes. Polyploidy and diplochromosomes
ere often seen with 50 μg/ml. Exposure of cells to
0, 30, or 50 μg/ml significantly enhanced the fre-
uency of morphological transformation. The mor-
hology of the transformed cells was indistinguishable from that of cells treated with N-methyl-N'-nitro-N-nitrosoguanidine. The health hazard resulting from environmental contamination by pyrolysis products should be investigated. (10 refs)

78-3469 **Mutation in Cultures Human Lymphoid Lines (Meeting Abstract).** (Eng) Bennett, S. (Div. Genetics, Coll. Physicians and Surgeons, Columbia Univ., New York, NY, 10032); Bloom, A.; Nakamura, F.; Spence, S. *Mutat Res* 53(1): 120; 1978. (no refs)

78-3470 **Chromosome Studies of Trichloroethylene Workers.** (Ger) Konietzko, H. (Institut fur Arbeitsmedizin der Universitat, Wilhelmstrasse 27, D-7400 Tubingen, W. Germany); Haberlandt, W.; Heilbronner, H.; Reill, G.; Weichardt, H. *Arch Toxicol (Berl)* 40(3): 201-206; 1978.

On the basis of lymphocyte cultures, chromosome studies were carried out on 28 employees involved in the purification of trichloroethylene (TCE) who were exposed from 1 to 21 yr to various concentrations of TCE. Nine of these subjects showed elevated numbers of hypodiploid cells, but otherwise they had normal karyotypes; one subject had the karyotype 47,XY,+mar (small metacentric extrachromosome). For these nine employees, it was found that the significantly higher chromosome aberration rate correlated with TCE concentration level but not with duration of exposure. (9 refs)

78-3471 **Chromosomal Aberrations in Heavy Smokers.** (Eng) Obe, G. (Institut fur Genetik, Freie Universitat Berlin, Arnimallee 5-7, D-1000 Berlin 33, W. Germany); Herha, J. *Hum Genet* 41(3): 259-263; 1978.

Lymphocyte chromosomes from 20 heavy smokers and 71 controls were examined after 48-hr culture for the frequency of dicentric chromosomes, ring chromosomes, and chromatid translocations. There was significant excess of chromosome and chromatid aberrations among the smokers. No chromosome exchanges were noted in 5/20, 2 of whom allegedly did not inhale. (21 refs)

78-3472 Changes in Shape and Orientation of Cell Nuclei due to Neoplastic Transformation. (Rus) Samoilov, V. I. (State Univ., Moscow, USSR); Rovenskii, Iu. A.; Slavnaia, I. L.; Slovachevskii, M. S. *Tsitologiia* 20(3): 321-328; 1978.

The ability to elongate and the contact orientation reaction of cell nuclei were studied in nine fibroblastlike transformed cell lines cultured on curved and flat polymer surfaces with radii of 333, 75, or 61 μm. The cell lines tested included a murine line L transformed by methylcholanthrene in vitro, murine lines C40 and C-khim (sarcomas induced by implantation of plastic material), murine line M22 transformed by simian virus 40 (SV40) virus in vitro, Syrian hamster cell line 20/90 transformed by SV40 virus in vitro, Syrian hamster cell line KhEK-40 transformed by cytomegalovirus in vitro, Syrian hamster cell line KP transformed by polyoma virus in vitro, rat cell line K2 transformed spontaneously in vitro, and human cell line ChETR transformed by SV40 virus in vitro. Normal embryonic fibroblasts of the respective species were used as controls. The elongation of the cell nuclei was reduced in the human, rat, Syrian hamster, and one of the murine cell lines cultured on flat substrate, compared with the corresponding controls. The elongation of the nuclei of the transformed cells failed to increase on the curved surface during the first 24 hr of culture, but a slight increase was observed during the following 24 hr. Contact orientation, ie, as the deviation of the orientation of the long axes of the cell nuclei from that of the axis of the cylinder, was absent or considerably reduced in the transformed cell lines, compared with the normal fibroblasts. 78-3474 Chromosome Changes (Trisomies #15 and 17) Associated with Tumor Progression in Leukemias Induced by Radiation Leukemia Virus. (Eng) Wiener, F. (Dept. Tumor Biology, Karolinska Institutet, 104 01 Stockholm 60, Sweden); Ohno, S.; Spira, J.; Haran-Ghera, N.; Klein, G. *J Natl Cancer Inst* 61(1): 227-237; 1978.

Chromosome changes associated with tumor progression in leukemias induced by radiation leukemia virus (RadLV) were investigated in C57BL/6 mice. Males were inoculated by various routes with RadLV variant-induced preleukemia a
leukemia cells from female inbred C57BL/6 mice. Since
donors were females and all recipients were males, the s
chromosome complements (XX and XY) were used to disti
guish the preleukemia and leukemia cells from those of h
origin. G-banding analyses revealed that $>50\%$ of the mal
that developed leukemia possessed tumor stem lines of
chromosomes with a trisomy of chromosome 15 (5/14 mi
that had received dependent RadLV-induced preleukem
cells and 12/14 mice that had received autonomo
RadLV-induced preleukemia cells). In animals inoculat
with overt leukemia cells and in which tumor progressi
occurred, G-banding analyses revealed an additional trisom
of chromosome 17. The cytogenetic evidence strongly su
gests that diploid preleukemia cells injected into syngene
recipients gain an additional chromosome 15 in the first sta
of leukemia development (during their transformation in
fully autonomous tumor cells). The results also indicate th
in some animals inoculated with overt leukemia cells, pr
sumably with a chromosome constitution of 41XX and tris
my of chromosome 15, leukemia progression is mark
cytogenetically by the further gain of genetic material in t
form of trisomy of chromosome 17. At present, the signi
cance of this second trisomy cannot be assessed. (33 refs)

**78-3475 Conversion of Polycythemia vera to Refractor
Anemia with Hyperplastic Bone Marrow.** (En
Mitrou, P. S. (Zentrum der Inneren Medizin, Abteilung f
Hamatologie, Johann Wolfgang Goethe-Universitat, The
dor-Stern-Kai, D-6000 Frankfurt am Main 70, W. Ge
many); Fischer, M.; Krehan, L.; Martin, H. *Blut* 36(1): 41-4
1978.

Five years after his last chemotherapeutic treatment (busu
fan) for polycythemia vera, a 46-yr-old man developed pa
cytopenia or refractory anemia with hyperplastic bone ma
row. The morphologic changes and the presence of blast cel
in bone marrow and peripheral blood suggested a prele
kemia state. The patient died within a year fro
bronchopneumonia. The nomenclature associated wi
this condition (pancytopenia, chronic erythroleukem
preleukemia) is not uniform, but the morpholog
findings are virtually identical. Some patients su
sequently develop acute leukemia. The prognosis
refractory anemia with hyperplastic bone marro
following polycythemia vera is, independent of the su
sequent acute leukemia, invariably terminal. (14 re

**78-3476 A Fatal Myeloproliferative Syndrome in
Family with Thrombocytopenia and Platel
Dysfunction.** (Eng) Luddy, R. E. (Dept. Pediatrics, Uni
Maryland Sch. Medicine, 22 S. Greene St., Baltimore, M
21201); Champion, L. A.; Schwartz, A. D. *Cancer* 41(5
1959-1963; 1978.

A family is described in which three children died of a myeloproliferative syndrome following a lifelong history of thrombocytopenia and a bleeding disorder. Two of the children had a disorder resembling juvenile chronic myelogenous leukemia and the third had acute monocytic leukemia. Hematologic abnormalities in the mother and five other siblings included thrombocytopenia, abnormal platelet function, elevated Hb F or serum vitamin B_{12} concentrations, and low WBC alkaline phosphatase scores. These leukemia-associated abnormalities in a family with multiple cases of nonlymphocytic leukemia appear to represent a previous undescribed familial myeloproliferative syndrome. (11 refs)

78-3477 **Thirteen Cases of Leukemia in a Family.** (Eng) Gunz, F. W. (Dept. Medical Res., Kanematsu Memorial Inst., Sydney Hosp., Sydney, New South Wales 2000, Australia); Gunz, J. P.; Vincent, P. C.; Bergin, M.; Johnson, F. L.; Bashir, H.; Kirk, R. L. *J Natl Cancer Inst* 60(6): 1243-1250; 1978.

Thirteen cases of leukemia, 12 of them acute, occurred in three generations of a family comprising 293 members. Individual cases could not be linked to the possession of any of a range of genetic markers. Cytogenetic studies showed no constitutional chromosome abnormalities. Preliminary results of virologic studies suggested the presence of oncornaviruses in at least one leukemic patient whose DNA contained sequences related to the RNA genome of baboon endogenous virus. This aggregation of leukemia cases likely resulted from a genetic, probably polygenic, predisposition in association with the activity of leukemogenic factors whose nature remains to be clearly defined. (21 refs)

78-3478 **Acute Leukemia in a Kidney Transplant Patient Treated with Immunosuppressants.** (Fre) Olmer, M. (Service de Nephrologie, Hopital de la Conception, 136, rue Saint-Pierre, F 13335 Marseille Cedex 4, France); Robert, A. *Nouv Presse Med* 7(1): 49; 1978.

Acute leukemia developed in 44-yr-old man 3 yr after he received a kidney transplant accompanied by treatment with immunosuppressants. The immunosuppressive therapy consisted of antilymphocyte serum for 15 days after the transplant and total doses of 4.5 g mercaptopurine and 57 g azathioprine. The patient was maintained on cortisone because of evidence of transplant rejection. Petechial purpura appeared suddenly, and a hematogram showed anemia, 2,500/mm^3 WBC, 10% polynuclear neutrophils, and the presence of blast cells. A myelogram showed a massive infiltration of leukoblasts (60%), most of which were monocyte precursors; the others were immature granulocytes. The patient died 9 days later, and autopsy confirmed the presence of leukemia with widespread hemorrhage. There was no history of contact with a chemical carcinogen, and serological tests for viral infection were negative except for the persistence of the Australia antigen. Possible mechanisms for the development of the leukemia in this patient are discussed. (6 refs)

78-3479 **Leukemia in Identical Twins.** (Eng) Fujimoto, T. (Dept. Pediatrics, Kyushu Univ. Sch. Med., Fukuoka, Japan); Hasegawa, K.; Take, H.; Miyazaki, S.; Sasaki, K.; Kishida, K.; Goya, N. *Acta Haematol Jpn* 41(1): 57-62; 1978.

Cases of concordant acute lymphocytic leukemia occurring in 3.5-yr-old identical twin boys are reported. Only one other report of concordant acute leukemia in identical twins has appeared in the Japanese literature. (17 refs)

78-3480 **Hibernoma: A Possible Model of Brown Fat Histogenesis.** (Eng) Dardick, I. (Dept. Lab. Medicine, Ottawa Civic Hosp., 1053 Carling Ave., Ottawa, Ontario K1Y 4E9, Canada). *Hum Pathol* 9(3): 321-329; 1978.

Hibernomas are composed of cells that resemble those of brown adipose tissue. A surgically resected hibernoma is described that contained cells at all stages of maturation from immature, relatively lipid-free cells to multiloculated and, finally, uniloculated adipocytes. The ultrastructural features of the adipocytes were compared with the previously reported features of differentiating preadipocytes and lipid-depleted mature adipocytes from human white adipose tissue. This comparison confirmed the existence of distinct mitochondrial and cytoplasmic membrane component differences at all developmental stages. Thus, brown and white adipose tissue may be two distinct histologic types. (34 refs)

78-3481 **Malignant Histiocytomas.** (Eng) Langsam, L. B. (Dept. Surgery, St. Vincent Charity Hosp., 2351 E. 22nd St., Cleveland, OH, 44115); Fine, G.; Ponka, J. L. *Arch Surg* 113(4): 473-476; 1978.

A review of 16 patients (13 men, 3 women aged 12-75 yr) with malignant histiocytomas in the extremities, head, chest wall, retroperitoneum, lung, spermatic cord, and lower abdomen is presented. Various methods of treatment were used; local recurrence developed in 29% treated with local excision. Ten patients are alive and well, two are alive with metastatic disease. These heterogeneous diseases probably arise from the histiocyte. (10 refs)

78-3482 **Possible Reversion of Malignancy In Vivo.** (Eng) Revilla, M. C. (Dept. Investigacion en Medicina Experimental, Lab. Biomembranas, Mexico DF, Mexico); Gonzalez, M. T.; Balderas, M. Z.; Romero, G. *Nature* 272(5652): 454-455; 1978. (5 refs)

The L5178Y lymphoma line, which is stable when passaged in syngeneic BALB/c mice and has a diploid chromosome number of 39 ± 1, was used to study the reversion of malignancy in vivo. When serially allotransplanted for up to eight passages in CD1 mice, the cells lost their tumorigenicity; they did not induce tumors when transplanted to BALB/c mice. The reversion state was associated with an increase in chromosome number from diploid to subtetraploid or tetraploid between the first and fifth transplantations, with a decrease to diploid or subdiploid between the sixth and eighth passages. The stability of the reverted cells is attributed to the balance between chromosome factors that determine the expression (E) and suppression (S) of transformed properties; ie, an excess of S over E. (5 refs)

78-3483 **Clonal Origin of a T Cell Lymphoproliferative Malignancy.** (Eng) Stryckmans, P. A. (Institut Jules Bordet, 1, rue Heger Bordet, Brussels, Belgium); Debusscher, L.; Heyder-Bruckner, C.; Heimann, R.; Mandelbaum, I. M.; Wybran, J. *Blood* 52(1): 69-76; 1978.

An attempt was made to determine the clonal origin of the circulating neoplastic T-cells of a 34-yr-old black woman with a T-cell lymphoproliferative malignancy and heterozygosity at the X Cap "ex" chromosome-linked locus for glucose-6-phosphate dehydrogenase (G-6-PD) isoenzymes. Light and electron microscopy revealed the lymphoid nature of the circulating tumor cells, which were identified as T cells by an erythrocyte (E) rosette assay. When the patient's peripheral WBC count reached 95 x 10^9/liter, 88% of the cells formed E rosettes. Electrophoresis showed equal staining of G-6-PD isoenzymes (A and B) in the RBC, the isolated peripheral blood mononuclear cells, the polymononuclear cells, and the T-cell-poor lymphocyte population. In contrast, heavy staining of G-6-PD-B and only traces of G-6-PD-A could be seen in the T-cell-rich population. After treatment of the patient, equal staining of both isoenzymes was seen in all cellular populations, including the T-cell-rich population. The observation that the G-6-PD was almost exclusively of the B type in the circulating neoplastic cells strongly suggests the monoclonal origin of this T-lymphocyte-derived malignancy. (29 refs)

78-3484 **Immune Function in Healthy Relatives of Patients with Malignant Disease.** (Eng) Dworsky, R. (Edmondson Res. Building, 1840 N. Soto St., Los Angeles, CA 90032); Baptista, J.; Parker, J.; Chandor, S.; Noble, G.; Herrmann, K.; Henle, W.; Henderson, B. *J Natl Cancer Inst* 60(1): 27-30; 1978.

Measures of humoral and cell-mediated immunity were compared in healthy members of 18 different families grouped according to their history of neoplasia. There were four groups. Group 1 had 22 members of 5 families with 2 or more cases of lymphoproliferative disease in first- and/or second-degree relatives, Group 2 had 11 members of 6 families in which the propositus had a lymphoreticular neoplasm and other cancers occurred in first- and/or second-degree relatives, Group 3 had 18 members of 7 families with no known history of cancer, and Group 4 consisted of 7 laboratory personnel and 4 spouses of participating families. Group 1 had a significantly lower response to concanavalin A (Con A) than Group 2 or 4. The difference in response to *Candida albicans* antigen between Groups 1 and 3 were also significant. Group 1 had a significantly higher IgM level; IgM was positively correlated to WBC counts. A negative correlation was found between Con A responses and both IgM level and Epstein-Barr virus-viral capsid antigen (EBV-VCA) titers. However, IgM and EBV-VCA were not strongly correlated with each other. EBV-VCA titers and measles antibody titers were correlated. EBV-VCA titers showed an inverse correlation with responses to phytohemagglutinin A and Con A mitogens. These findings indicate that healthy members of families with multiple cases of lymphoma may have decreased responses to mitogen stimulation compared with members of families with other forms of cancer. (21 refs.)

78-3485 **Melanogenesis in Genetically Determined Pigment Cell Tumors of Platyfish and Platyfish-Swordtail Hybrids: Correlation Between Tyrosinase Activity and Degree of Malignancy.** (Eng) Vielkind, U. (Genetisches Institut, Justus-Liebig-Universitat Giessen, Heinrich-Buff-Ring 58-62, D-6300 Lahn-Giessen, W. Germany); Schlage, W.; Anders, F. *Z Krebsforsch* 90(3): 285-299; 1977.

Tyrosinase activity was determined in the soluble and particulate fractions of tumors in platyfish (*Platypoecilus maculatus*) and platyfish-swordtail (*Xiphophorus helleri guentheri*) hybrids. A close correlation was observed between the level of tyrosinase activity and the degree of malignancy. Spot patterns consisting of completely differentiated (benign) tumor gene (Tu)-transformed cells showed no tyrosinase activity. Premelanomas containing a few incompletely differentiated (malignant) Tu-transformed cells in addition to many differentiated ones showed moderate tyrosinase activities. Melanomas which contained increasing numbers of incompletely differentiated cells with increasing growth rates showed high to extremely high tyrosinase activities. Thus, tyrosinase levels can be used as indicators of both the degree of differentiation and degree of malignancy of neoplastically transformed pigment cells. (49 refs)

78-3486 **Actual Doubling Time Values of Pulmonary Metastases from Malignant Melanoma.** (Eng)

Plesnicar, S. (Inst. Oncology, Vrazov trg 4, 61000 Ljubljana, Yugoslavia); Klanjscek, G.; Modic, S. *Aust NZ J Surg* 48(1): 23-25; 1978.

The doubling times of small- and large-diameter pulmonary metastases were compared in 18 patients (9 men, 9 women 24-89 yr old) with pulmonary metastases from histologically proved malignant melanoma. From chest radiograms, 81 metastases were measured 51 consecutive times and 120 doubling-time values were obtained. These values were calculated according to the change in tumor diameter. Metastases with diameters ≤15.0 mm grew significantly faster (mean doubling time 24.9 days) than metastases with diameters > 15.0 mm (mean doubling time 51.0 days). Eleven values were > 100 days (mean: 182.2 days); the diameters of the metastases ranged from 100 to 397.8 mm. The group rate appears to depend on the size of the metastatic growth, since with increasing volume of metastases the growth rates seemed to decrease. (11 refs)

78-3487 **Isolation and Metastatic Properties of Detachment Variants of B16 Melanoma Cells.** (Eng) Briles, E. B. (Div. Hematology, Washington Univ. Sch. Medicine, Box 8125, 660 South Euclid, St. Louis, MO, 63110); Kornfeld, S. *J Natl Cancer Inst* 60(6): 1217-1222; 1978.

Variant clones of B16 melanoma cells (B16F1 and B16F10 lines) were studied for the relationship between their in vitro adhesive properties and their in vivo tumor-related properties. Variant clones were isolated that detached from plastic tissue culture dishes either more or less readily than the parent lines upon treatment with EDTA or ethyleneglycol-bis(b-aminoethylether)-N,N-tetraacetic acid. Cells that detached more readily were spindlier in culture than parent cells, covered less surface area per cell, and formed fewer pulmonary tumors when injected iv into syngeneic C57BL/6J mice. Cells that detached less readily were flatter in culture and formed more pulmonary tumors when injected iv than the parent cells. After detachment with EDTA, the cells reattached to culture dishes at the same rate. This result is discussed in terms of the concept that initial attachment and subsequent establishment of cell-to-substrate adhesions (ie, cell spreading) are independent events. (21 refs)

78-3488 **Effects of Enzymes and Polyelectrolytes on the Aggregation Properties of Metastatic Melanoma Cells (Meeting Abstract).** (Eng) Madyastha, K. R. (Div. Medical Oncology, Medical Coll. Virginia, Richmond, VA, 28298); Phondke, G. P.; Madyastha, P. R.; Barth, R. F. *Proc Am Assoc Cancer Res* 19: 221; 1978. (no refs)

78-3489 **A Case of Oculocutaneous Albinism Complicated by Malignant Melanoma.** (Jpn) Yoshioka, J. (Dept. Dermatology, Nara Medical Univ., Kashihara, Japan); Kitamura, W. *Jpn J Clin Dermatol* 32(5): 355-364; 1978.

A 32-yr-old woman with oculocutaneous albinism, an autosomal recessive condition, developed a malignant melanoma. She had been treated with dopa-R (dihydroxyphenylalanine-R) and melanin for the albinism. Types II and III melanosomes were found among the tumor cells. Eight literature cases of benign and malignant tumors developing in human albinos are also reported. (24 refs)

78-3490 **Amyloidoma: A Clinicopathologic Study of Four Cases (Meeting Abstract).** (Eng) Lipper, S. (Dept. Pathology, Univ. Cape Town Medical Sch., Cape Town, South Africa); Kahn, L. B. *Lab Invest* 38(3): 354-355; 1978. (no refs)

78-3491 **Precursor Lesions in Familial Melanoma: A New Genetic Preneoplastic Syndrome.** (Eng) Reimer, R. R. (Dept. Hematology-Oncology, Cleveland Clinic Foundation, 9500 Euclid Ave., Cleveland, OH, 44106); Clark, W. H.; Greene, M. H.; Ainsworth, A. M.; Fraumeni, J. F. *JAMA* 239(8): 744-746; 1978.

Examination of seven melanoma-prone families revealed that 18/20 melanoma patients and 24/43 first-degree relatives had prominent pigmented cutaneous lesions. The lesions were flat, frequently > 10 mm in diameter, and haphazardly colored. The number of lesions ranged from 10 to > 100 per person. They were most common over the "horse collar" area of the trunk and upper extremities, but they were also present on unexposed areas. Examination of six persons with this syndrome showed level 1 or 2 superficial spreading melanomas arising from one of the lesions. The detection rate of melanoma among first-degree relatives with the syndrome was 14%. This syndrome appears to represent an autosomal dominant trait, and it may serve as a cutaneous marker to identify persons at high risk for melanoma. (12 refs)

78-3492 **Osteogenesis and Chondrogenesis in Transplants of Dunn and Ridgway Osteosarcoma Cell Cultures.** (Eng) Hanamura, H. (Dept. Surgery, Div. Orthopedic Surgery, UCLA Medical Sch., Los Angeles, CA); Urist, M. R. *Am J Pathol* 91(2): 277-298; 1978.

The effects of Dunn and Ridgway osteosarcoma cells and cell products on the genetic program of normal connective tissue cells were determined. Dunn osteosarcomas synthesized 2 times more alkaline phosphatase than Ridgway osteosarcomas, 3 times more than HeLa cells, and 4-5 times more than rat or mouse fibroblast cell cultures. Implants of killed freeze-dried Dunn cell cultures into the thigh muscles of mice were resorbed and replaced by normal cartilage, bone, and bone marrow tissue. Implants of freeze-dried Ridgway cells were resorbed and replaced by fibrous tissue only. Outgrowths of normal muscle septum connective tissue cells into the stroma of Ridgway tumors differentiated into fibrous tissue. Cultures of either tumor on a substratum of bone matrix stroma prepared from normal bone proliferated, assumed a spherical shape, and perpetuated the transformed osteoblast-like cell without forming attachments or adapting to the contour of the substratum. Outgrowths of muscle mesenchymal cells on the Dunn tumor stroma differentiated into cartilage. Dunn osteosarcoma cell cultures proliferated on the inside and produced deposits of normal bone (not tumorous bone) on the outside of diffusion chambers. Killed freeze-dried cell cultures produced transfilter deposits of normal bone and bone marrow, but in significantly lower quantity. Outgrowths of muscle connective tissue, on a substratum of cellulose acetate, differentiated into cartilage when cell-free Dunn stroma was present under the organ culture grid. Tumorigenesis and normal cartilage and bone morphodifferentiation were antithetic; however, tumor cells transferred a bone morphogen similar to the bone morphogenetic protein (BMP) of normal bone matrix. BMP recruited mesenchymal cells to proliferate and differentiate into cartilage and bone. (32 refs)

78-3493 **Separation of Cells from a Murine Fibrosarcoma on the Basis of Size. II. Differential Effects of Cell Size and Age on Lung Retention and Colony Formation in Normal and Preconditioned Mice.** (Eng) Grdina, D. J. (Section Experimental Radiotherapy, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., 6723 Bertner Ave., Houston, TX, 77030); Peters, L. J.; Jones, S.; Chan, E. *J Natl Cancer Inst* 61(1): 215-220; 1978.

The influence of cell size and cell age on the intrinsic clonogenicity and retention efficiency of tumor cells in relation to lung colony formation (LCF) was investigated in female C3Hf/Bu mice inoculated iv with fibrosarcoma cells (2 x 10^5 viable cells). Three different lung colony assays were used to study the influence of these parameters in normal untreated mice and in mice in which the efficiency of the assay was increased by pretreatment (24 hr before inoculation) with cyclophosphamide (CP) (250 mg/kg, sc) or whole-body irradiation (WBI: 1,000 rads). Mice receiving WBI also received 10^6 heavily irradiated cells (10,000 rads) in the viable cell inoculum. In untreated mice, cell retention and LCF were positively correlated, with the larger cells, predominantly in G_2, being the most efficiently retained and yielding the most lung colonies. No effect of cell size or relative position in the cell cycle on LCF was seen in preconditioned mice. The efficiency of LCF was increased by 10- and 30-fold in CP and WBI-treated mice, respectively. Cell arrest patterns correlated with LCF in WBI-treated mice for all cell sizes, but no such correlation was found for the smallest cells (G_1 phase) in CP-pretreated mice. It is concluded that the intrinsic clonogenic ability of a fibrosarcoma cell does not depend on its size or its relative position in the cell cycle. Inasmuch as the metastatic ability of a cell is a function of both its intrinsic clonogenic ability and its relationship to host-modifying factors, the parameters of cell size and age can, however, become important determinants in metastasis formation, depending on the conditions imposed on the host. (15 refs)

78-3494 **Pathology of Immunologic Regression of Tumor Metastases in the Lymph Nodes.** (Eng) Kodama, T. (Lab. Pathology, Cancer Inst., Hokkaido Univ. Sch. Medicine, Kita-15-jo, Nishi-7-chome, Kita-ku, Sapporo 060, Japan). *Gann Monogr Cancer Res* (20): 83-91; 1977.

The pathology of a transplantable lymphosarcoma (WGT4) induced by Gross virus in WKA/Mk rats was investigated. Injection of 5 x 10^6 tumor cells into the right foot of Gross-tolerant rats resulted in death from tumor growth in approx 16 days. However, injection of tumor cells into normal rats showed temporary growth followed by regression. All WGT-4 tumors regressed completely in an av of 16 days. The right popliteal, lumbar, and inguinal lymph nodes draining the tumor site in Gross-tolerant rats enlarged with tumor growth and reached a max size at death. Lymph nodes from normal rats reached a max size on day 8 and returned to normal after approx 16 days. By day 6 after tumor cell injection, the regional lymph nodes were completely occupied by tumor in both Gross-tolerant and normal rats; however, lymph node metastases disappeared in normal rats by day 8. Histopathologically, infiltration and proliferation of lymphoid cells, reticulum cells, and fibrocytes occurred in the regressing metastatic tumor and in the regressing transplanted tumor in the foot. Uninfected rat lymph nodes, in which metastases regressed, had a 'starry sky' appearance. These findings suggest that regression of transplanted or metastatic tumors in syngeneic rats is due to an immunological reaction by the host and that immunological factors may be responsible for the 'starry sky' appearance of the node. (19 refs)

78-3495 **Regulation of Development of Embryo-derived Teratocarcinomas (Meeting Abstract).** (Eng) Damjanov, I. (Hahnemann Medical Coll., Philadelphia, PA, 19102); Caldwell, J. W. *Lab Invest* 38(3): 384; 1978. (no refs)

78-3496 **Isolation and Characterization of Chromatin from Embryoid Bodies and Teratomas: Role of Nonhistone Chromosomal Proteins in Differentiation (Meeting Abstract).** (Eng) Carter, D. B. (Lab. Environmental Toxicology, NIEHS, Research Triangle Park, NC, 27709). *Environ Health Perspect* 20: 238-239; 1977. (no refs)

78-3497 **Histogenesis of Dermatofibrosarcoma Protuberans. An Ultrastructural Study.** (Eng) Alguacil-Garcia, A. (Section of Publications, Mayo Clinic and Mayo Foundation, Rochester, MN 55901); Unni, K. K.; Goellner, J. R. *Am J Clin Pathol* 69(4): 427-434; 1978.

Three original and two recurrent lesions of dermatofibrosarcoma protuberans (DFP) from five patients were studied ultrastructurally. The basic tumor cell was spindle-shaped, with long slender cytoplasmic projections (CP). The nuclei were usually fusiform, and they showed some convolutions and indentations. In cross section, the nuclei were ovoid, or less frequently, very lobulated or cerebriform. The cytoplasmic membrane was smooth. The cytoplasm contained scant profiles of flat rough endoplasmic reticulum, a few vesicles of smooth endoplasmic reticulum, mitochondria, and free ribosomes and polyribosomes. Variable numbers of tumor cells showed fragments of basal lamina, small focal cytoplasmic densities peripherally, and, rarely, maculae adherens-type intercellular junctions. The latter were usually seen between the CP. The tumor cells and their CP were often arranged in a circular fashion around the CP of other tumor cells. This sheath-like arrangement was very characteristic of DFP. The tumor cells had a strong resemblance to pericytes and perineural cells, as well as marked ultrastructural similarities to neurofibroma. These findings suggest that DFP arises from a primitive fibroblastic cell with a sheath-forming cell differentiation simulating perineural cells. (37 refs)

78-3498 **Xeroderma Pigmentosum. Clinical Course and Ultrastructure of Tumor-free Skin Regions Not Exposed to Sun.** (Ger) Haustein, U. F. (Hautklinik des Bereichs Medizin, Karl-Marx-Universitat, Liebigstrasse 21, DDR-701 Leipzig, E. Germany). *Dermatol Monatsschr* 164(4): 255-270; 1978.

In a 29-yr-old woman with xeroderma pigmentosum (XP), the poikilodermatic, precancerous stage of the disease was observed in parallel with the neoplastic stage. Since childhood, the patient had developed many epidermal, mesenchymal, and pigment-forming tumors that had been treated surgically, radiologically, or with ointments containing 5-fluorouracil. Electron microscopy of tumor-free skin that had not been exposed to the sun revealed the following: (1) distinct changes of the keratinocytes and basal cells; (2) polymorphism as well as elevated and premature synthesis of (pre)melanosomes; and (3) vacuolization of the upper corium and changes resembling elastosis senilis in fibroblasts with an otherwise normal structure. These changes are comparable to those observed after UV irradiation. Elevated melanin synthesis may be an attempt to compensate for the UV effect by morphologic changes parallel to the development of lentigo maligna. (53 refs)

78-3499 **Histologically Proved Basal Cell Carcinomas in Identical Twins.** (Eng) Liddell, K. (District General Hosp., Eastbourne, E. Sussex BN21 2UD, England). *Br Med J* 2(6130): 97; 1978.

Identical twins (65 yr old) presented with at virtually the same time with erythematous, slightly crusted lesions of the back, which were diagnosed histologically to be superficial basal cell carcinoma. Common epidemiological factors (possibly, arsenical salts taken in tonics as children) and inherited biochemical defect are suggested as possible causes. (4 refs)

78-3500 **Multiple Bowen's Disease Observed in Former Workers of a Poison Gas Factory in Japan, with Special Reference to Mustard Gas Exposure.** (Eng) Inada, S. (Dept. Dermatology, Hiroshima Univ. Sch. Medicine, Kasumi, Hiroshima 734, Japan); Hiragun, K.; Seo, K.; Yamura, T. *Jpn J Dermatol B* 5(2): 49-60; 1978.

Five cases of multiple Bowen's disease in former employees of a poison gas factory in Okunojima, Japan, were studied. The patients, all men, ranged in age from 63 to 70 yr (mean, 66 yr), and they had been employed in the production of mustard gas for 3-15.3 yr (mean, 9.3 yr). The period between commencement of employment in the factory and diagnosis of Bowen's disease ranged from 31 to 46 yr (mean, 39.2 yr). A total of 23 lesions of Bowen's disease were identified on the five patients: 10 on the trunk, 3 on the upper extremities, and 10 on the lower extremities. Although the workers wore protective clothing, the mustard gas permeated the clothing and apparently dissolved in the sweat to affect the skin. In addition to the Bowen's lesions, all patients had numerous pigmented and depigmented spots and hyperkeratotic papular eruptions on the skin. These data suggest that the Bowen's disease in these workers was caused by exposure to mustard gas, although there are no literature reports of this association. (35 refs)

78-3501 **Mycosis Fungoides: Can Continuous Antigen Stimulation Be Its Cause?** (Fre) Bazex, J. (Clinique des Maladies Cutanees et Syphilitiques, Hopital Purpan, Place du Dr. Baylac, F 31052 Toulouse Cedex, France). *Nouv Presse Med* 22(16): 1410; 1978.

Three patients developed mycosis fungoides several years after the implantation of metallic bone prostheses. The symptoms disappeared a few weeks after the implants were removed. The findings suggest continuous antigen (metal, in this case) stimulation as the possible cause of mycosis fungoides in these patients. (4 refs)

78-3502 **Malignant Meningioma: Ultrastructure and Observations on Histogenesis.** (Eng) Pietruszka, M. (Dept. Pathology, Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA); Salazar, H.; Pena, C. *Pathology* 10(2): 169-173; 1978.

A malignant meningioma was studied by light and electron microscopy. Histologically, the tumor was composed predominantly of spindle shaped cells arranged in interlacing bundles with numerous mitoses and frequent nuclear atypia. Tonguelike projections of tumor infiltrated the cerebral cortex, dura mater and blood vessels. Necrotic foci were conspicuous. Ultrastructurally, the main findings included moderate plasma membrane interdigitation, many intracytoplasmic filaments, and junctional attachments of three kinds: desmosomes, hemidesmosomes, and zonulae adherens. These subcellular features are suggestive of an arachnoidal cell origin. (9 refs)

78-3503 **Subependymoma. A Case Report with Ultrastructural Study.** (Eng) Azzarelli, B. (Inst. Pathology, Case Western Reserve Univ., Cleveland, OH 44106); Rekate, H. L.; Roessmann, U. *Acta Neuropathol (Berl)* 40(3): 279-282; 1977.

Light and electron microscopic examination of a subependymoma in a 68-yr-old man showed that it probably arose by replication of mature subependymal tissue. The designation subependymoma is indicative of both its geographic and cytogenetic origin. It should not be designated an astrocytoma or an ependymoma. (9 refs.)

78-3504 **Selection and Altered Properties of Brain-colonising Metastatic Melanoma.** (Eng) Brunson, K. W. (Dept. Developmental and Cell Biology, Univ. California, Irvine, CA, 92717); Beattie, G.; Nicolson, G. L. *Nature* 272(5653): 543-545; 1978.

Sequential in vivo selection for brain-preferring B16 melanoma variant lines yielded cell lines that became more brain-specific with selection. The B16-F1 line (selected once in the lung), yielded a large number of pulmonary tumors, some extrapulmonary tumors, and a few brain tumors. Brain-selected B16-B5 and B16-B10n lines formed larger numbers of brain lesions and few to almost no lung tumors or lesion at other sites. Cell-surface differences between brain-selecte and lung-selected B16 melanoma lines were found when exposed surface proteins were analyzed by lactoperoxidas catalyzed iodination. Autoradiograms made after sodiu dodecyl sulfate-polyacrylamide gel electrophoresis of ^{125}I labeled surface proteins from the B16 lines revealed that th brain-selected lines had a predominance of two exposed surface proteins of mol wt 95,000 (95K) and 100K, compare with the parental B16-F1 line. The degree of exposure of th 95K and 100K proteins correlated with the degree of brai colonization and preference in 5/5 experiments (B16-B10 > B16-B5 > B16-B1 = (approx) B16-F1). Because bot surface proteins were labeled on the B16-F line, th indicates possible differences in the display or quantit of these surface molecules on the brain-colonizing B1 B lines. (36 refs)

78-3505 **Primary Intracranial Tumours in Black and Indian Children, 1960-1975.** (Eng) Quinn, R. J (Dept. Paediatrics and Child Health, Univ. Natal, Durban S. Africa); Scragg, J. N.; Rubidge, C. J. *S Afr Med J* 53(6) 211-213; 1978.

The results of a survey of primary intracranial tumors occurring in children admitted to King Edward VIII Hospital i Durban between 1960-1975 are presented. Of 60 childre identified, 42 were black and 18 were Indian to give respectiv incidences of 0.5 and 2.1/1,000 admissions. Comparison wit the number of children admitted with other malignant diseases showed cerebral tumors to be the most common form of solid neoplasms in children <12 yr of age. Thirty tumor were supratentorial and 29 were infratentorial; the exact primary site could not be established in 1. Histological type wa determined in 49 cases, with astrocytoma (26) and medulloblastoma (12) being the most common tumors. The age distribution, sex ratio, and tumor site of these patients were simila to those found in recent studies of other racial groups. (8 refs)

78-3506 **Medulloblastoma: Example of Late Adult Onset with Statistical Correlation Relative to Etiology.** (Eng) Seitz, W. S. (Inst. Medical Analysis, Bockgasse 4.9.9, A-1120 Vienna, Austria); Operschall, E. J. *Radiol Clin (Basel)* 47(4): 295-309; 1978.

A unique case of advanced adult onset of medulloblastoma in a 88-yr-old Chinese woman is reported, and the literature on 33 histologically verified cases of medulloblastoma is reviewed. The patient underwent craniotomy and excision of a posterior fossa cerebellar tumor that demonstrated ovoid or elongated tumor cells with hyperchromatic nuclei in a configuration suggesting a classical medulloblastoma without typical rosette formation. The patient died 8 mo after surgery. A review of the literature and data compiled by the California

Tumor Registry reveal that this case represents the oldest example of medulloblastoma, which appears to occur most frequently around the age of 5 yr. The male to female ratio is 2.04 for all age groups. Since 1971, the av survival has increased from 25 to 27 mo, possibly as a result of improved therapeutic techniques. The changing survival expectancy with surviving interval is 10 mo/survival yr. There is a relationship between prognosis and histological type, tumor location, age, and sex. The literature also reveals that there is a trend for adult lateral and child midline development, lending support to the etiological concept of migration of primitive medulloblasts upward and laterally to form the external granular layer. There is a statistically significant tendency for midline tumors to differentiate along classical lines and lateral tumors along desmoplastic lines. (25 refs)

78-3507 **Grave Cranio-cerebral Trauma 30 Years Ago as Cause of the Brain Glioma at the Locus of the Trauma. Particulars of the Case.** (Eng) Mrowka, R. (Klinika Neurochirurgii, Slaskiej Acad. Medicine, ul. Medykow 14, P1-40752 Katowice 6, Poland); Bogunska, C.; Kulesza, J.; Bazowski, P.; Wencel, T. *Zentralbl Neurochir* 39(1): 57-64; 1978.

A glioblastoma multiforme developed in a 50-yr-old man 30 yr after he suffered a craniocerebral trauma caused by the penetration of artillery missile splinters in the left parietal region. A 3-cm bone defect was located directly above the tumor, and there were close cicatrical connections among the dura, brain tissue, and tumor. (18 refs)

78-3508 **Colon Polyps, Sebaceous Cysts, Gastric Polyps, and Malignant Brain Tumor in a Family.** (Eng) Binder, M. K. (Div. Gastroenterology, Dept. Medicine, Harbor General Hosp., 1000 W. Carson St., Torrance, CA, 90509); Zablen, M. A.; Fleischer, D. E.; Sue, D. Y.; Dwyer, R. M.; Hanelin, L. *Am J Dig Dis* 23(5): 460-466; 1978.

A family with a distinct syndrome of adenomatous colonic polyps and sebaceous cysts without osseous or soft-tissue abnormalities is presented. One member had benign gastric polyps limited to the upper half of the stomach and another had a medulloblastoma of the cerebellum. A histologic feature in the colon of the propositus was the presence of atypical epithelium in flat mucosa as well as in the colonic polyps. The atypical epithelium, which was noted after subtotal colectomy, may be the earliest stage of new polyp formation and further malignant potential. The grandfather in this family had colon cancer, and a granduncle had gastric carcinoma. (15 refs)

78-3509 **The Relation of Nervous Elements to Intradermal Nevi. An Electron Microscopic Study.** (Eng) Jurecka, W. (Institut fur Mikromorphologie und Elektronenmikroskopie, Universitat Wien, Alser Strasse 4, A-1090 Vienna, Austria); Lassmann, H.; Gebhart, W. *Arch Dermatol Res* 261(3): 219-230; 1978.

Intratumoral nerves of dermal nevi were investigated by electron microscopy in order to determine the role of neural elements in the development of these tumors. Intratumoral nerves exhibited an increased cellularity, but the number of myelinated fibers was reduced. Types B and C nevus cells were frequently present within the nerve fascicles. Unmyelinated axons were found in close relationship to nevus cells. Schwann cells showed proliferations similar to the early stages of neurofibroma, and they could be differentiated from unpigmented tumor cells by their relation to axons only. These findings indicate that identical cell populations are present within the intratumoral nerves and the tumor itself. Therefore, the theory of a neural component in the histogenesis of intradermal nevi is supported. (26 refs)

78-3510 **Ultrastructural Study of Cellular Relationships in Squamous Cell Carcinomas (Meeting Abstract).** (Eng) Gigoux, C. (Univ. Rochester, Rochester, NY); Johansen, E.; Norante, J. D. *J Dent Res* 57(A): 261; 1978. (no refs)

78-3511 **Distant Metastases in Nasopharyngeal Carcinoma.** (Eng) Khor, T. H. (Dept. Radiotherapy, Singapore General Hosp., Singapore 3); Tan, B. C.; Chua, E. J.; Chia, K. B. *Clin Radiol* 29(1): 27-30; 1978.

The records of 352 consecutive patients with nasopharyngeal carcinoma (NPC) were analyzed to determine the pattern of distant metastases, which were diagnosed on the basis of clinical signs and radiography. Ninety-nine patients (28.1%) developed distant metastases. There were no age or sex differences in risk. Skeletal metastases occurred in 48.5% of metastatic cases. Lung and liver involvement followed at frequencies of 30.3% and 29.3%, respectively. Of the 21 double organ combinations, bone and lung (7 cases) and bone and liver (6 cases) were the most common. The extent of the primary tumor and the cervical lymph node status both exerted a significant influence on the probability of metastases developing. Sixty-five (65.6%) patients with subsequent distant metastases had no local disease clinically, either in the nasopharynx or the cervical lymph nodes. The prognosis of NPC patients with metastases is poor, with a median survival under 4 mo and a mortality rate of 91% within a year of the first metastasis. (12 refs)

78-3512 **Investigations on the Occurrence and Stages of Various Forms of Thyroid Carcinoma in an En-**

demic Goiter Area (Meeting Abstract). (Ger) Lohrs, U. (Munich, W. Germany); Permanetter, W.; Spelsberg, F.; Beitinger, M. *Zentralbl Allg Pathol* 122(1/2): 144; 1978. (no refs)

78-3513 **Association of Thymoma and Thymic Lymphoid Hyperplasia (Meeting Abstract).** (Eng) Madarnas, P. (Dept. Pathology, Univ. Sherbrooke, Sherbrooke, Quebec, Canada). *Lab Invest* 38(3): 355; 1978. (no refs)

78-3514 **Teratomas of the Neck in Adults.** (Eng) Colton, J. J. (Dept. Otorhinolaryngology, Univ. Michigan Hosp., Ann Arbor, MI, 48109); Batsakis, J. G.; Work, W. P. *Arch Otolaryngol* 104(5): 271-272; 1978.

The 10th case of malignant teratoma of the neck in an adult (77-yr-old man) is reported. The clinicopathologic features of these tumors are different in adults and in neonates/infants. The tumors may arise from germ cells and/or displaced multipotential embryonic tissue. A proposed pathogenesis is that tissue about the primitive streak and notochord lose its governing external influences and develop into tumors. The reason for the long dormant period is not known. (7 refs)

78-3515 **Enhancement of the Tumorigenicity of Preneoplastic Mammary Nodule Lines by Enzymatic Dissociation.** (Eng) Medina, D. (Dept. Cell Biology, Baylor Coll. Medicine, Texas Medical Center, Houston, TX, 77030); Shepherd, F.; Gropp, T. *J Natl Cancer Inst* 60(5): 1121-1126; 1978.

The effects of enzymatic dissociation on the tumor potentials were examined in three preneoplastic mammary nodule lines (D1, D2, and C4) isolated from BALB/cCrgl mice. Treatment with collagenase, hyaluronidase, and pronase or with collagenase and hyaluronidase produced high yields of viable single cells that were injected (10^5 cells) into the cleared mammary fat pads of syngeneic BALB/c mice. In 11 experiments, all dissociated nodule cell lines showed a marked increase in tumorigenicity, compared with the same tissues transplanted as 1-mm^3 pieces. The results could not be explained on the basis of differences between the amounts of cells transplanted in the two procedures. In a second series of experiments, normal mammary cells from virgin, pregnant, or lactating mice were mixed in different ratios with 10^5 nodule cells and injected into the mammary fat pads. The presence of the normal cells reversed the marked increase in the tumorigenicity of the enzymatically dissociated nodule cells to a level equal to or less than the tumorigenicity of control transplants (1-mm^3 pieces). The growth of 10^5 mammary tumor cells was not inhibited when the cells were mixed with 3 x 10^5 normal cells and transplanted into the mammary fat pads. These results showed that enzymatic dissociation can increase the tumor potential of preneoplastic mammary nodule lines. They support the hypothesis that nodule cells, but not neoplastic cells, are sensitive to the growth-inhibitory effects of normal mammary cells. (18 refs)

78-3517 **Intravascular Mucinosis and Thrombosis Accompanying Adenocarcinomas (Meeting Abstract).** (Eng) Pratt-Thomas, H. R. (Dept. Pathology, Medical Univ. South Carolina, Charleston, SC, 29403); Smith, R. M.; McMaster, K. R.; Earlywine, G. R. *Lab Invest* 38(3): 361; 1978. (no refs)

78-3518 **Cytomorphological Grading and Feulgen DNA-Analysis of Metaplastic and Neoplastic Bronchial Cells.** (Eng) Nasiell, M. (Dept. Pathology, Sabbatsberg Hosp., Box 6401, S-113 82 Stockholm, Sweden); Kato, H.; Auer, G.; Zetterberg, A.; Roger, V.; Karlen, L. *Cancer* 41(4): 1511-1521; 1978.

Quantitative determinations of nuclear DNA were made in sputum cytology specimens with diagnoses of metaplasia; metaplasia with borderline, mild, moderate, or severe atypia; carcinoma in situ; and invasive carcinoma. An attempt was made to determine if progressive atypia and neoplasia are related to changes in DNA content. The cellular material was processed by the destaining diagnostic smears and processed by destaining the diagnostic smears and restaining them by the Feulgen method. Nuclear DNA content was determined with a scanning microspectrophotometer. There was good correlation between increasing degree of aneuploidy and increasing degree of morphologic nuclear atypia. The data also indicate a progressive aberration from normality of nuclear DNA content in squamous metaplastic and neoplastic cells exhibiting a progressive degree of atypia. This implies that squamous bronchial carcinoma is preceded by sequential changes in cellular composition that can be detected by quantitative DNA analysis and cytology. (15 refs)

78-3519 **Endogenous Factors in Bronchial Carcinoma.** (Ger) Kohout, J. (Medizinische Abteilung, Wilhelminenspital, Montleartstrasse 37, A-1171 Vienna, Austria). *Wien Med Wochenschr* 128(4): 1-8; 1978.

Bronchial carcinoma and its possible relationships with other diseases were studied in a series of 224 patients. Lung carcinoma was found to be associated with chronic bronchitis in 195/224 patients, but there were no significant differences in the incidence of chronic bronchitis among the different histological types of the carcinoma. Chronic bronchitis was found in 87/99 cases of squamous cell carcinoma, 37/42 cases of adenocarcinoma, 33/37 cases of small cell carcinoma, 35/41 cases of giant cell carcinoma, and 3/5 cases of alveolar cell carcinoma. Lung carcinoma was associated with chronic gastric or duodenal ulcer in 39 cases, with other chronic gastrointestinal diseases in 39, with chronic pulmonary tuberculosis in 21, with chronic cholecystopathy in 21, with liver cirrhosis or chronic hepatitis in 19, and with chronic sinusitis, tonsillitis, or otitis in 18. The distribution of these chronic diseases was independent of the histological type of the carcinoma. The skin window test revealed weakened and delayed macrophage activity in the carcinoma patients, independent of the histological type. These findings and the fact that the recent increase in lung cancer incidence is mainly due to an increase in the incidence of squamous cell carcinoma indicate the absence of an evident causal relationship between lung carcinoma and any accompanying chronic diseases. The reduced macrophage activity observed in both the lung carcinoma and these diseases may be a common cause of their chronic course and frequent association. (26 refs)

78-3520 **Unusual Coincidence of Carcinoma of the Stomach and Bronchi.** (Cze) Zdichynec, B. (Vnitrni oddeleni, nemocnice s poliklinikou Pocataky, OUNZ, Pelhrimov, Czechoslovakia). *Cesk Gastroenterol Vyz* 31(8): 554-556; 1977.

Carcinomas of the bronchi and stomach with metastases to the liver, adrenals, kidneys, and pericardium were found in a 52-yr-old man who smoked > 40 cigarettes a day. The incidence of gastric and bronchial carcinoma in relatives of the same generation was 5/16 and 2/16, respectively. (6 refs)

78-3521 **Morphologic Aspects of Experimental Canine Bronchial Carcinogen Exposure.** (Eng) Cohen, A. H. (Dept. Pathology, Harbor General Hosp., 1000 W. Carson St., Torrance, CA, 90509); Shors, E.; Okita, M.; Matsumura, K.; Jensen, T.; Benfield, J. R. *Eur J Cancer* 14(4): 401-409; 1978.

Alterations in canine bronchial epithelium were studied during the course of recurrent localized carcinogen exposure. Five groups of dogs were used. Group 1 (7 mongrels) received submucosal injections of 3 ml of a solution containing 15 mg/ml benzo(a)pyrene (BP) attached to a ferric acid carrier for a total dose of 810 mg over 32 mo. Group 2 (8 mongrels) received submucosal injections of 3 ml of a solution containing 10-15 mg/ml N-methyl-N-nitrosourea (MNU) for a total dose of 810-945 mg over 28 mo. Group 3 (6 mongrels) received BP similar to Group 1 for 11 mo and then mucosal application of 0.5 ml of a solution containing 10 mg/ml NMU for 16 mo. Group 4 (12 inbred beagles) and Group 5 (21 inbred beagles) received submucosal injections of 0.5 ml of a solution containing 30 mg/ml BP for 7 mo (total dose 315 mg) and mucosal application of 0.5 ml of a solution containing 30 mg NMU for 17 mo (total dose 135 mg). Group 5 dogs were treated with azathioprine and prednisolone to achieve chronic immunosuppression. The initial lesion was hyperplasia of the columnar cells with occasional intraepithelial gland formation. Basal cell hyperplasia and squamous metaplasia ensued and were frequently coexistent. Atypical epithelial maturation was noted in all dogs, especially those with squamous metaplasia. The immunosuppression regimen indicated that antibody responses were depressed within 2 mo, skin graft rejection was prolonged, and cutaneous responses to injected antigens were suppressed, compared to Group 4. Thus, the dog is an ideal model for studying the sequence of events during the induction of bronchial carcinomas. (20 refs)

78-3522 **Enhancement of Artificial Lung Metastases in Tumor-Bearing Mice (Meeting Abstract).** (Eng) Ando, K. (M. D. Anderson Hosp. and Tumor Inst., Houston, TX 77030); Hunter, N.; Peters, L. J. *Proc Am Assoc Cancer Res* 19: 172; 1978. (no refs)

C. *In: Carcinogens: Identification and Mechanisms of Action. Proceedings of the Thirty-First Annual Symposium on Fundamental Cancer Research Held at Houston, Texas, 1-3 March 1978.* University of Texas System Cancer Center, M. D. Anderson Hospital and Tumor Institute, NCI, American Cancer Society. (Austin, Texas). 20-21 pp.; 1978. (no refs)

78-3524 **Isoniazid and Bile Duct Cancer (Letter to Editor).** (Eng) Lowenfels, A. B. (Westchester County Medical Center, Valhalla, NY); Norman, J. *JAMA* 240(5): 434-435; 1978.

Two men (55 and 71 yr old) developed bile duct cancer 18 and 2 yr after receiving isoniazid (total dose, 122 and 36 g, respectively) for pulmonary tuberculosis. The short interval in the latter patient may have been due to the fact that he was an alcoholic. These were the only bile duct cancers seen at this hospital from 1970 to 1977. (3 refs)

78-3525 **Management of Congenital Choledochal Cyst with Intrahepatic Involvement.** (Eng) Todani, T. (Dept. Surgery, Okayama Univ. Medical Sch., Okayama, Japan); Narusue, M.; Watanabe, Y.; Tabuchi, K.; Okajima, K. *Ann Surg* 187(3): 272-280; 1978.

Observations of 75 patients (17 personal cases and 58 from the literature) with choledochal cysts with intrahepatic involvement (Type IV-A) indicated that surgical treatment must achieve bile drainage from both choledochal and intrahepatic sites. To prevent cancer at a later age, hepaticoenterostomy at the porta hepatis with partial resection of the wall of the intrahepatic cyst combined with excision of the intrahepatic cyst is recommended. Six of the 75 patients developed cancer. (34 refs)

78-3526 **Retrograde Lymphatic Spread of Colonic Carcinoma to the Liver.** (Eng) Kumar, R. K. (Sch. Pathology, Univ. New South Wales, Kensington, New South Wales 2033, Australia). *Experientia* 34(6): 768-769; 1978.

A case is presented of retrograde lymphatic permeation of the liver by a colonic carcinoma. A 63-yr-old man underwent hemicolectomy for a moderately differentiated adenocarcinoma of the cecum. Three months later, multiple metastatic nodules were found in the abdominal wall and mesentery. He died 1 mo later. Autopsy findings indicated that the carcinoma had recurred at the site of previous anastomosis. There was no evidence of contiguous spread of the tumor. The liver contained no metastatic nodules, but the carcinoma had spread along the neurovascular-ductal bundles arising from the porta hepatis and had involved lymph nodes in the porta hepatis. Microscopic examination revealed a moderately differentiated adenocarcinoma that had infiltrated the submucosal, muscular, and serosal layers of the intestine at the anastomotic sites. In the liver, there was extensive malignant infiltration of the major portal tracts. It is concluded that this case illustrates the typical features of retrograde lymphatic permeation of the liver by a malignant tumor. (4 refs)

78-3527 **Non-tropical "Idiopathic Splenomegaly": a Follow-up Study of Ten Patients Described in 1969.** (Eng) Dacie, J. V. (Dept. Haematology, Royal Postgraduate Medical Sch., Ducane Road, London W12 0HS, England); Galton, D. A.; Gordon-Smith, E. C.; Harrison, C. V. *Br J Haematol* 38(2): 185-193; 1978.

The history of 4/10 patients who were reported in 1969 as suffering from nontropical idiopathic splenomegaly is given. Of the remaining six patients, two had been lost to follow-up and four had died: two from lymphoma 4.5 yr and 8 mo, respectively, after splenectomy and two from unrelated causes. Two of the four living patients developed malignant lymphomas 6 and 2 yr, respectively, after splenectomy. The other two have lived for 17 and 15 yr, respectively, without developing any signs of a malignant tumor. One of the lymphoma patients was treated successfully by x-radiation; the other patient was initially treated successfully by x-radiation and chemotherapy and is still alive, although the tumor is now resistant to chemotherapy. The histology of the patients' spleens was reviewed in the light of their clinical history, but no criteria were found that would be of prognostic value. However, some cytological abnormality was recognized in the spleens of 3/4 patients who developed malignant lymphomas. It appears that unless the cell population in both the red and white pulp is strictly normal, the patient is likely to develop a malignant lymphoma. The tumors that subsequently developed had no special or characteristic features. (5 refs)

78-3528 **Effects of Culture Conditions on the Growth and Differentiation of Transformed Rat Adrenocortical Cells.** (Eng) Auersperg, N. (Cancer Res. Center, Univ. British Columbia, Vancouver, British Columbia, V6T 1W5, Canada). *Cancer Res* 38(7): 1872-1884; 1978.

Depending on culture conditions, normal rat adrenocortical (AC) cells grown in vitro either proliferate and are fibroblast-shaped, with myoid cell characteristics and limited steroidogenic activity, or they do not replicate and are epitheliallike and similar to AC secretory cells structurally and steroidogenically. The effects of oncogenic transformation on these cellular responses were investigated in the Kirsten murine sarcoma virus-transformed rat AC line TRA. Transformation eliminated the differential proliferative response of the cells to culture variables and resulted in similar growth rates and high cell densities under all conditions. Horse serum, conducive to epitheliallike growth of untransformed cells, caused aggregation, but fetal calf serum, conducive to fibroblastic growth of untransformed cells, caused dispersed growth in TRA cultures. Variations in dissociation procedures had little effect on growth patterns. Most ultrastructural characteristics of myoid as well as AC differentiation were reduced in TRA cells; basement membranes and extracellular matrix were produced, but under different conditions than those in untransformed cultures. Like normal AC cells, TRA cells were capable of 20α-reduction and Δ^5-3-β-dehydrogenation of ^{14}C-pregnenolone but, in contrast to untransformed cells, they did not respond to variables in culture conditions by qualitative changes in pregnenolone metabolism, they did not produce deoxycorticosterone or corticosterone, and they secreted progesterone, which was not recovered from untransformed cultures. TRA cells showed no increase in steroidogenic differentiation in response to culture environment factors that normally modulate fibroblast-shaped AC stem cells to more differentiated steroid-secreting cells. (33 refs)

78-3529 **Adrenocortical Carcinoma in Two Children with Subsequent Primary Tumors.** (Eng) Levine, G. W. (Dept. Pathology, Children's Hosp., 1056 E. 19th Ave., Denver, CO, 80218). *Am J Dis Child* 132(3): 238-240; 1978.

The case reports of two unrelated 13-mo-old children with adrenocortical carcinoma who subsequently developed another primary tumor are presented. In both patients, the tumor was removed surgically, and no specific antitumor therapy was given. In one child an intracerebellar medulloblastoma was diagnosed at age 5, and in the other a poorly differentiated ileocecal lymphocytic lymphoma was diagnosed at age 8. Since neither child had a history suggestive of exposure to environmental agents and iatrogenic causes can be excluded as a factor in the tumorigenesis, it is suggested that these patients had a genetic predisposition to tumor development. None of the parents exhibited an immune defense deficit. (17 refs)

78-3530 **Wilms Tumor in a Mother and Child.** (Eng) Tebbi, K. (Dept. Pediatrics, Case Western Reserve Univ., Rainbow Babies & Childrens Hosp., 2101 Adelbert Road, Cleveland, OH, 44106); Gross, S. *J Pediatr* 92(6): 1026-1027; 1978.

The occurrence of Wilms' tumor in a mother and son is reported. Both had undergone left nephrectomy, at ages 1 yr and 5 yr, respectively, for the tumor. No abnormalities were noted in three siblings. The son is free of recurrent disease 2 yr later. Neither the mother nor the child had identifiable chromosomal abnormalities. It has been suggested that for hereditary Wilms' tumor, a mutation in the germinal cells of one parent is inherited by the infected offspring, but a second mutation in the somatic cells is necessary for tumor development. (7 refs)

78-3531 **Inflammatory Oncotaxis.** (Eng) DerHagopian, R. P. (Div. Surgical Oncology, Univ. Miami, Sch. Medicine, P.O. Box 520875, Miami, FL, 33152); Sugarbaker, E. V.; Ketcham, A. *JAMA* 240(4): 374-375; 1978.

The presence of long disease-free intervals prior to cancer recurrence supports the concept of the dormant neoplastic cell. Clinical and experimental observations suggest that tissue trauma and subsequent inflammation enhance the implantation and growth of circulating cancer cells at trauma sites or that dormant neoplastic cells at these sites may undergo metamorphosis and growth. Brief reports of four recent cases of tumor recurrence following trauma and inflammation are offered as examples. The term oncotaxis is used to convey the overall picture of cancer cell attraction to points of inflammation. Inflammation is oncotactic because it facilitates entrapment of tumor cells and provides capillary stickiness and disruption in the intercellular endothelial barrier. Whether there are actual substances similar to chemotactic products that attract WBC is speculative. Inflammation is only one potential cause for facilitating metastases. (9 refs)

78-3532 **Highly Differentiated Gastric Adenocarcinoma Originating from the Normal, Non-metaplastic Gastric Epithelium. An Ultrastructural Study of a Case.** (Eng) Teglbjoerg, P. S. (Inst. Pathology, Odense Univ. Hosp., DK-5000 Odense, Denmark). *Acta Pathol Microbiol Scand [A]* 86(1): 87-89; 1978.

Light microscopic and ultrastructural features of a highly differentiated gastric adenocarcinoma are presented. The specimen was collected during a total gastrectomy performed on a 69-yr-old man who had complained of increasing dyspepsia for 6 mo. By light microscopy, the tumor was classified as a pylorocardiac gland carcinoma. Incomplete microvilli could be observed by electron microscopy at the luminal cytoplasmic membrane. There were plentiful spherical, electron-dense secretory granules in the luminal part of the cytoplasm. Identical secretory granules were seen in the pyloric glands of normal nonneoplastic mucosa removed from another stomach. The cells of these glands also had incomplete microvilli. This ultrastructural study provides considerable evidence that the tumor had its origin in the normal, nonmetaplastic gastric epithelium, possibly the pylorocardiac glands. (10 refs)

78-3533 **Cancer of the Cardia Misdiagnosed as Hiatal Hernia.** (Fre) Ballivet, M. (Centre Hospitalier Princesse Grace, av. Pasteur, Monaco, Principality Monaco); Fissore, A.; Fissore, O.; Campora, J. L.; Annonier, C. *Sem Hop Paris* 54(3): 155-156; 1978.

Cancer of the cardia of the stomach was discovered in a 70-yr-old man who underwent surgery for a hiatal hernia. An extreme narrowing of the esophagus at the esophagogastric junction had prevented endoscopic examination of the stomach. The original diagnosis was hiatal hernia with peptic esophagitis. (no refs)

78-3534 **Genetic Aspects of Gastritis-Cancer Relationship.** (Eng) Varis, K. (Gastroenterological Unit-ed Second Dept. Medicine, Meilahti Hosp., SF-Helsinki, Finland); Ihamaki, T.; Lehtola, J.; Sipponen, F.; Kekki, M.; Isokoski, M.; Saukkonen, M.; Siurala, M. *Dtsch Z Verdau Stoffwechselkr* 38(2): 51-54; 1978.

Genetic studies of three family samples comprising first-degree relatives of probands with severe atrophic body gastritis, pernicious anemia, and gastric carcinoma were performed to evaluate the genetic background and precancerous significance of atrophic gastritis. The studies indicated that the tendency to develop severe atrophic body gastritis is influenced by one genetic factor and that this genetically caused type of gastritis is connected with a higher risk of developing gastric carcinoma. There is, however, no conclusive evidence that atrophic gastritis alone leads to gastric carcinoma. It is possible that it makes the gastric mucosa more prone to the effects of factors that initiate the promotion phase of the malignant process. It is also possible that atrophic gastritis and gastric carcinoma are parallel phenomena with some common genetic factors.(7 refs)

78-3535 **Genetic and Dynamic Views on Gastritis-Cancer Relationship (Meeting Abstract).** (Eng) Varis, K. (Gastroenterological Unit, Second Dept. Medicine, Meilahti Hosp., Univ. Helsinki, Helsinki, Finland); Kekki, M.; Lehtola, J.; Ihamaki, T.; Sipponen, P.; Isokoski, M.; Saukkonen, M.; Siurala, M. *Digestion* 16(3): 281-282; 1977. (no refs)

78-3536 **Cancer Risk of the Stomach Resected for Ulcer: The Influence of the Gastroenteric Anastomosis (Meeting Abstract).** (Eng) Dahm, K. (Chirurgische Universitatsklinik, Hamburg, W. Germany); Eichfuss, H. P.; Koch, W. *Digestion* 16(3): 236; 1977. (no refs)

78-3537 **Follow-Up of Patients with Chronic and Atrophic Gastritis for the Question of Precancerous State (Meeting Abstract).** (Eng) Bergemann, W. (Geriatric Dept., Second Internal Dept., General Hosp., Berlin-Wilmersdorf, W. Germany). *Digestion* 16(3): 230-231; 1977. (no refs)

78-3538 **Gastric Lesions in Familial Adenomatosis Coli. Their Incidence and Histologic Analysis.** (Eng) Watanabe, H. (Second Dept. Pathology, Faculty Medicine, Kyushu Univ., 60, Fukuoka 812, Japan); Enjoji, M.; Yao, T.; Ohsato, K. *Hum Pathol* 9(3): 269-283; 1978.

The frequency of accompanying gastric lesions in familial adenomatosis coli (FAC) was investigated in 22 patients from 14 families. Various gastric lesions were confirmed in 15 patients belonging to 13 families. Histologically, the lesions were classified as adenoma (9), fundic gland polyposis (6), carcinoma (3), and microcarcinoid (2). Fundic gland polyposis consisting of simple hyperplasia of the fundic glands may be the gastric lesion specific to FAC, since polyposis has not been reported in any other disease. FAC affects not only the colon and rectum, but is capable of inducing tumorigenicity in other organs. The stomach is one of the organs in which extracolonic lesions occur. (35 refs)

78-3539 **Malignant Transformation of Hyperplasiogenic Polyps of the Stomach. Case Report.** (Eng) Remmele, W. (Pathologisches Inst., Kliniken der Landeshauptstadt Wiesbaden, Schwalbacher Strasse 62, D-6200 Wiesbaden, W. Germany); Kolb, E. F. *Endoscopy* 10(1): 63-65; 1978.

Examination of hyperplasiogenic gastric polyps from a 71-yr-old woman revealed the presence of adenocarcinoma in two polyps. It is suggested that a biopsy diagnosis of hyperplasiogenic polyp be followed by removal of the whole polyp to prevent or halt malignant transformation. In view of this instance of transformation, the classification of hyperplasiogenic polyps as hyperplastic should be reevaluated. (8 refs)

78-3540 **Duodenal Ulcer Associated with Pyloric Microgastrinoma and Antropyloric Focal Gastrinosis.** (Fre) Berger, G. (Laboratoire d'Anatomie Pathologique de l'UER, Alexis Carrel Hopital Cardiologique, B. P. Lyon Monchat, F 69394 Lyon Cedex 3, France); Chayvialle, J. A.; Berger, F. *Nouv Presse Med* 7(22): 1937-1940; 1978.

A small benign gastrinoma of the pylorus and focal gastrinosis were discovered in the vagotomy-antrectomy specimen of a 59-yr-old man with symptoms of duodenal ulcer. The ulcer symptoms were of 20 yr duration and had recently increased in intensity. X-rays and gastric endoscopy revealed a duodenal ulcer. Despite medical treatment, the symptoms persisted. Initial exploration of acid secretion and blood gastrin levels in response to iv secretin (3 IU/kg/hr) showed only a slight elevation in gastrin levels and no abnormalities in acid secretion. A second exploration 3 mo later showed a moderate but stabilized increase in blood gastrin levels and acid secretion that led to the tentative diagnosis of gastrinoma or hyperplasia of the gastrin-producing antral cells. No pathology was observed during vagotomy-antrectomy; after the surgery, the and blood gastrin level fell to below normal levels. Examination of the surgical speciman showed a tiny (0.5 cm) submucosal carcinoid tumor (gastrinoma) with an ulcerated surface. It had not infiltrated the muscle layer. The gastrin cells in the tumor were revealed by immunocytochemical tests with antigastrin serum. Gastrin cells were also observed in the antropyloric region. The role of these minimal gastrin cell lesions in the pathogenesis of duodenal ulcer and their relationship to the Zollinger-Ellison syndrome are discussed. (12 refs)

78-3541 **Adenocarcinoma of the Lower Third of the Duodenum. Diagnosis by Endoscopy and Radiology.** (Fre) Debray, C. (Clinique des Maladies de l'Appareil digestif, Service de Gastro-enterologie A, Hopital Bichat, 170, boulevard Ney, 75877 Paris Cedex 18, France); Charleux, H.; Gouerou, H.; Richard, P.; Marche, C. *Sem Hop Paris* 54(3): 172-175; 1978.

A 35-yr-old woman developed an adenocarcinoma of the lower third of the duodenum, a rare location (0.033%-0.05% at autopsy). Endoscopy with 11 biopsies and 2 x-ray series were necessary to diagnose the 3-cm neoplasm, which was located 9 cm from the pylorus. The patient had a duodenectomy, a pancreatectomy of the head of the pancreas, and a cholecystectomy, and she was well 1 yr after surgery. (no refs)

78-3542 **Three Antral Lesions: Two Neoplasms (One on the Site of an Ulcer Scar) and an Accessory Pancreas.** (Fre) Debray, C. (Service de Gastro-enterologie A, Clinique des Maladies de l'Appareil digestif, Hopital Bichat, 170 boulevard Ney, 75877 Paris Cedex 18, France); Leymarios, J.; Benhamou, G.; Marche, C. *Sem Hop Paris* 54(3): 163-167; 1978.

The resected stomach of a 70-yr-old man had three lesions in the antral region. The first lesion was a differentiated carcinoma superimposed on a gastric ulcer, the second was a differentiated adenocarcinoma, and the third was a 9-mm accessory pancreas. (no refs)

78-3543 **Induction of Pancreatic Ductulitis in Syrian Hamsters Transplanted with Pancreatic Adenocarcinoma (Meeting Abstract).** (Eng) Runge, R. G. (Eppley Inst. Cancer Res., Univ. Nebraska Medical Center, Omaha, NB, 68105); Pour, P.; Takahashi, M. *Proc Am Assoc Cancer Res* 19: 184; 1978. (1 ref)

78-3544 ***Streptococcus bovis* Endocarditis and Colonic Cancer (Letter to Editor).** (Eng) Noble, C. J. (Dept. Medical Microbiology, King's College Hosp., London, SE5 8RX, England); Uttley, A. H.; Falk, R. H.; Richardson, P. J. *Med J Aust* 1(8067): 766; 1978.

A 60-yr-old man presented with a short history of wt loss, rectal bleeding, and altered bowel habit 5 mo after admission for *Streptococcus bovis* endocarditis. Secondary hepatic deposits of well-differentiated adenocarcinoma were found, and the primary lesion was assumed to be the large bowel. In view of the eight literature cases of this association, it is suggested that *S. bovis* endocarditis patients be screened for carcinoma of the colon. (1 ref)

78-3545 **Promotion of Intestinal Neoplasia by Postoperative Mucosal Hyperplasia (Meeting Abstract).** (Eng) Williamson, R. C. (Bristol Royal Infirmary, Bristol, England); Bauer, F. L.; Ross, J. S.; Malt, R. A. *Digestion* 16(3): 284-285; 1977. (no refs)

78-3546 **Intestinal Polyposis: A Genetic Disease.** (Fre) Plauchu, H. (Service de Genetique, Hotel Dieu, F 69288 Lyon Cedex 1, France); Bigay, D.; Casteu, J. G.; Guillemin, G.; Robert, J. M. *Lyon Med* 239(1): 21-30; 1978.

The genetic and clinical aspects of intestinal polyposis are discussed based on a study of 32 cases in 22 families. A study of four family trees revealed variable expression of the responsible gene. It is suggested that familial polyposis coli has a genetic link with Gardner's syndrome and, perhaps, with Turcot's syndrome. (47 refs)

78-3547 **The Significance of Cholecystectomy in Colonic Carcinogenesis (Meeting Abstract).** (Ger) Werner (Hamburg, W. Germany); de Heer; Mitschke *Zentralbl Chir* 103(6): 378; 1975. (no refs)

78-3548 **Familial Colon Cancer.** (Fre) Sarroca, C. (Department de Chirurgie, Hopital Central des Forces Armees, Montevideo, Uruguay); Quadrelli, R.; Praderi, R. *Nouv Presse Med* 22(16): 1412; 1978.

Familial colonic cancer without polyposis was found in four generations of one family. The cancer was associated with cancer of the skin, pancreas, stomach, and endometrium and with acanthosis of the lips in some members. (no refs)

78-3549 **Human Ovarian Tumours Heterotransplanted to "Nude" Mice.** (Eng) Kullander, S. (Dept. Obstetrics and Gynaecology, Univ. Lund, Lund, Sweden); Rausing, A.; Trope, C. *Acta Obstet Gynecol Scand* 57(2): 149-159; 1978.

The acceptance, growth, and histology of 22 different human ovarian tumors, which were heterotransplanted sc to female nude mice, were studied. When small tissue pieces were used, 10/16 tumors grew. When tumor cell suspensions were used, however, all 11 trials failed. Metastatic or infiltrative growth was not seen in mice observed for up to 25-40 days. Material from each tumor was transplanted to four separate sites in two mice. The successful grafts largely retained the original morphological features. As measured by ^{3}H-thymidine incorporation, DNA synthesis was also similar in the original tumors and the growing grafts. Preliminary lactic dehydrogenase isoenzyme analysis of mouse venous blood several weeks after grafting showed that the original human tumor isoenzyme picture was mirrored in the mouse blood. Only one of the tumors from six previously treated patients grew. Irradiation and the cytostatic drugs might directly or indirectly have influenced cellular multiplication, DNA synthesis, and the possibilities of these damaged cells growing in the nude mouse. (22 refs)

78-3550 **The Ultrastructure of Endometrioid Carcinomas of the Ovary.** (Eng) Fenoglio, C. M. (Columbia Univ. Coll. Physicians and Surgeons, New York, NY, 10032); Puri, S.; Richart, R. M. *Gynecol Oncol* 6(2): 152-164; 1978.

Tissue samples from 12 histologically documented cases of human ovarian endometrioid carcinoma were examined by light microscopy, scanning electron microscopy, and transmission electron microscopy. Eight of the 12 cases were well- or moderately well-differentiated neoplasms composed of cells arranged in a glandular pattern resembling malignant glands of the uterine endometrium. Seven of these contained cell types other than classical endometrial cells: 4 contained areas of clear cells, 3 were associated with squamous metaplasia (adenoacanthoma), 2 contained mucinous or serous components, and in 1 case there was associated endometriosis. The ultrastructural features of these cases is described in detail. In general, the cells were pleomorphic and arranged irregularly, and most of the cell surfaces were covered with abundant and well-developed microvilli. The most characteristic feature of the endometriallike cells was bundles of perinuclear microfilaments and intracytoplasmic glycogen. The dominant cytoplasmic organelles were free ribosomes. Mitochondria, lysosomes, lipid droplets, and multivesicular bodies were also present. The plasma membranes in the apical regions were usually straight and reinforced by numerous desmosomes, but in the basal region they were irregular and connected with fewer and less well-developed desmosomes. A well-developed basal lamina was present. The nuclei were enlarged and ovoid, with well-defined nuclear membranes, solitary nucleoli, and chromatin material clumped at the periphery. Light microscopy can be used to diagnose well- and moderately well-differentiated lesions, but electron microscopy should be used for poorly differentiated cancers. (14 refs)

78-3551 **Uterine Choriocarcinoma Fourteen Years Following Bilateral Tubal Ligation.** (Eng) Lathrop, J. C. (Dept. Gynecology, Rhode Island Hosp., Providence, RI); Wachtel, T. J.; Meissner, G. F. *Obstet Gynecol* 51(4): 477-482; 1978.

A 42-yr-old woman developed a choriocarcinoma of the uterus 14 yr after bilateral tubal ligation and resection and 15 yr after the birth of her last (fourth) child. Chromosomal studies of cultured metastatic cells from a metastatic lung nodule and the skin revealed an extra number 8 chromosome in a subpopulation of cells. The tumor could have arisen from a new pregnancy, but no fistula between the peritoneal cavity and tube or endometrial cavity could be demonstrated or it could have arisen de novo as a nongestational lesion. However, it is most likely that the lesion resulted from the activation of chorionic cells that had probably been present since the patient's last pregnancy. (15 refs)

78-3554 **Precancerous Potential of Condyloma of the Cervix and the Vagina (Meeting Abstract).** (Eng) Commisso, J. (Dept. Cytology, Magee-Womens Hosp., Pittsburgh, PA); Kanbour, A.; Fisher, E.; Klionsky, B. *Acta Cytol (Baltimore)* 21(6): 786; 1977. (no refs)

78-3555 **The Possible Role of Hemidesmosomes in Neonatally Estrogen-induced Selection of a Permanently Altered Abnormal Vaginal Epithelium.** (Eng) Cunha, G. R. (Anatomy Dept., Sch. Medicine, Univ. Colorado, Denver, CO, 80262); Lee, A. K. *J Exp Zool* 203(3): 361-370; 1978.

The involvement of hemidesmosomes in estradiol-induced vaginal epithelial cell selection was studied in neonatal BALB/c Crgl mice inoculated daily with 20 μg estradiol-17β (E). The number of hemidesmosomes per basal cell cross section (HD/bccs) of the vaginal epithelium increased gradually in both untreated and E-treated mice from 0.07 on day 1 to 2-3 on day 4. It then increased markedly on day 5, plateauing at 8 days at about 6-7 HD/bccs in the untreated mice and 14-15 in the E-treated mice. Approx 20 HD/bccs were observed in the vaginas of 57-day-old E-treated mice. Five-day-old E-treated mice contained two types of vaginal epithelial cells: basophilic cells containing about 19 HD/bccs and light cells containing only about 5 HD/bccs. The results suggest that electron-lucent basal cells with few HC/bccs are replaced in E-treated mice by basophilic, HD-rich cells. The data are consistent with the view that hormone-induced selection of vaginal epithelial cells whose expression of cornification and proliferation is independent of estrogen stimulation is accomplished by a selective increase in the numbers of hemidesmosomes in certain basal epithelial cells. (18 refs)

78-3556 **Hemopoietic Tissue Reactions Associated with the Growth of Transplanted Syngeneic Murine Tumors.** (Rus) Osipova, T. V. (Lab. Virology, Cancer Res. Center, Moscow, USSR); Bukhman, V. M.; Belianchikova, N. I.; Svet-Moldavskii, G. Ia. *Biull Eksp Biol Med* 85(3): 346-349; 1978.

The leukemoid reactions induced by transplanted syngeneic solid tumors were studied in (CBA x C57BL/6j) mice. Animals were inoculated sc with hemangiopericytoma cells (10^6 tumor cells/mouse), urinary bladder carcinoma cells, or hepatoma cells (the last two at 0.5 ml of 50% homogenate). Hemangiopericytoma transplantation resulted in a marked increase in spleen wt, spleen cell cellularity, and the number of colony-forming units. These changes were first observed on day 2 after tumor transplantation. Tumor growth was correlated with an increase in WBC (the number of mature neutrophils showed a 10-fold increase, and the number of monocytes showed a 10- to 20-fold increase). The leukemoid reaction was less pronounced in mice with the transplanted hepatoma. Animals with the transplanted urinary bladder tumor did not show any increase in spleen wt and cell cellularity. The only change noted was an increased number of mature granulocytes (60%, compared to 10%-20% in controls). (12 refs)

78-3557 **Cytological Changes due to Urinary Calculi. A Consideration of the Relationship Between Calculi and the Development of Urothelial Carcinoma.** (Eng) Beyer-Boon, M. E. (Dept. Cytopathology, Univ. Medical Centre, Leyden, Netherlands); Cuypers, L. H.; de Voogt, H. J.; Brussee, J. A. *Br J Urol* 50(2): 81-89; 1978.

Cytological abnormalities that may occur during the presence of urinary calculi and after their removal were investigated in 62 lithiasis patients, and the relationship between calculi and the development of urothelial carcinoma was studied in 92 patients with cancer of the renal pelvis and ureter. In 11/62 lithiasis patients, the calculi induced urothelial cellular abnormalities comparable with those associated with malignancy. Severe cellular changes, comparable with those of carcinoma in situ, were observed in the epithelium adjacent to a calculus. Squamous metaplasia was frequently observed in cases with staghorn stones in the renal pelvis. The abrasive effect of the calculus could have accounted for the many multinucleated cells found in the sediment. Upon removal of the calculi, the cytological atypia and the multinucleation disappeared. To date, none of these patients has developed urothelial carcinoma. According to the hospital records of 92 patients with cancer of the renal pelvis and ureter, 14 had either concomitant or previous lithiasis. This finding indicates that lithiasis is more common than would be expected in patients with renal pelvic and ureter cancer, suggesting a relationship between these conditions. (34 refs)

78-3558 **Morphologic Characterization of Two Established Cell Lines, T24 and MGH-U1, Derived from Human Bladder Carcinoma.** (Eng) Kato, T. (Dept. Urology, Akita Univ. .Sch. Medicine, Akita, Japan); Ishikawa, K.; Nemoto, R. *Jpn J Urol* 69(1): 40-46; 1978.

The morphology of two established cell lines, T24 and MGH-U1, derived from human bladder transitional cell carcinomas was investigated. Light microscopy revealed that both lines retained their epithelial features and grew in a multilayered pattern. Scanning electron microscopy indicated that the cells had microvilli as well as cytoplasmic protrusions on the cell surface. Transmission electron microscopy revealed junctional complexes between adjacent cells and well-developed cytoplasmic organelles. Viruslike particles were not detected. In the proliferating phase, the cells had a polymorphic appearance; electron microscopy failed to detect morphologically distinct cells. In spite of the high degree of similarity between the two lines, T24 had slightly more spindle-shaped cells and more relatively well-developed microvilli, compared with MGH-U1 cells. T24 cells had a modal chromosome number of 91, but MGH-U1 cells had one of 85. These findings indicate that T24 cells underwent a change in their morphologic appearance following long-term culture. (14 refs)

78-3559 **Occult Urinary Bladder Cancer Associated with Prostatic Hyperplasia or Cancer (Meeting Abstract).** (Eng) Kahan, A. (Dept. Pathology, Montefiore Hosp. and Medical Center, Bronx, NY); Schreiber, K.; Koss, L. G. *Acta Cytol (Baltimore)* 21(6): 788; 1977. (no refs)

78-3560 **Carcinosarcoma of the Urinary Bladder.** (Ita) Martinelli, G. (Istituto de anatomia e istologia pathologica, II Cattedra, Universita di Bologna, Bologna, Italy); Bazzocchi, F.; Piccaluga, A.; Reggiani, A.; Buli, P.; Bercovich, E. *Pathologica* 69(998): 613-622; 1977.

Carcinoma intermingled with chondrosarcoma was found in the urinary bladder of a 59-yr-old man. The combination carcinosarcoma is assumed to have originated from a single embryonic germ cell with potential epithelial and mesenchymal evolution. (10 refs)

78-3561 **The Natural History of Nephrogenic Adenoma of the Urinary Bladder.** (Eng) Cremer, H. (Pathologisches Institut, Universitat Bonn, Postfach 2120, D-5300 Bonn 1, W. Germany); Adolphs, H. D. *Z Krebsforsch* 91(1): 49-53; 1978.

The natural history of a nephrogenic adenoma of the urinary bladder is presented based on four biopsies from a 64-yr-old patient. The adenoma was composed of both villous and glandular structures. The two-layered surface epithelium consisted of an eosinophilic cell layer covering a clear cell layer. The latter rested on a delicate basal layer. The clear cells disappeared toward the tip of the villi. There was a 200-μm zone of transition between the urinary bladder epithelium and the nephrogenic adenoma. Scattered nodules of glandular structures were found at the base of the villi, and they were lined by eosinophilic cells or by clear cells. These epithelial cells were derived from the corresponding surface epithelial cells from which they had separated by active downward growth. (8 refs)

78-3562 **The Association Between Vesical Carcinoma and Urinary Obstruction.** (Eng) Fellows, G. J. (Dept. of Urology, General Infirmary, Leeds, England). *Eur Urol* 4(3): 187-188; 1978.

Signs of bladder outflow obstruction were recorded in 199 male patients with carcinoma of the bladder and in an age-matched control group. The incidence of obstruction in the patients was significantly higher than that in controls ($p < 0.05$) and it increased with age in both groups. The most common cause of obstruction in this series was benign prostatic hyperplasia. (3 refs)

78-3563 **Adenomatoid Tumour of the Epididymis: Histochemical and Ultrastructural Study of 2 Cases.** (Eng) Nistal, M. (Departamento de Morfologia, Facultad de Medicina, Universidad Autonoma, c/Arzobispo Morcillo 4, Madrid 34, Spain); Contreras, F.; Paniagua, R. *Br J Urol* 50(2): 121-125; 1978.

The histochemical and ultrastructural characteristics of adenomatoid epididymal tumors that occurred in two patients (46 and 51 yr old) are described. Acid mucopolysaccharides were present in the lumen of the tubular structures. The epithelial cells had numerous microvilli in the free surface, junction complexes, wide intercellular channels, and a well-developed Golgi complex. Abundant bundles of microfilaments and intracellular spaces were observed in the cytoplasm. Both lymphocytes and histiocytes were identified in the tubular lumen and between the epithelial cells. The stroma of the tumor was composed of dense connective tissue with abundant bundles of elastic fibers. These findings support the concept that these tumors are of mesothelial origin. This is the first time that intracytoplasmic spaces in the epithelial cells and elastic fibers in the stroma have been observed. (3 refs)

78-3564 **Unusual Incidence of Testicular Tumors.** (Eng) Gordon, J. O. (Urology Professional Assoc., 605 Garfield St., Tupelo, MS, 38801); Elliott, J. P.; Evans, J. W.; Platt, L. O.; Gordon, A. M. *South Med J* 71(4): 372-373; 1978.

The case of three men, ages 27, 49, and 36, with seminoma are presented. Although this is a rare tumor, all three men were seen by the same physician within 18 mo. Follow-up of the patients revealed no evidence of recurrence or metastases following radiotherapy and tumor excision. (1 ref)

78-3565 **Mortality from Carcinoma of the Cervix.** (Eng) Yule, R. (Christie Hosp., Holt Radium Inst., Withington, Manchester M20 9BX, England). *Lancet* 1(8072): 1031-1032; 1978.

Although deaths from cervical cancer in England and Wales decreased in the period 1970-1976, the number of deaths in women > 35 yr old doubled. This increase is attributable to the earlier onset of sexual activity and to the increased use of contraceptive pills or intrauterine devices, which offer no protection against the transmissible agent (virus or spermatozoa) thought to be responsible for the disease. Widespread and frequent cytotesting is necessary to ensure the detection of precancerous cervical conditions in younger women. (no refs)

78-3568 **Epidemiology of Bladder Cancer Deaths in Japan.** (Eng) Ohno, Y. (Dept. Preventive Medicine, Nagoya Univ. Sch. Medicine, 65 Tsurumai-cho, Showa-ku, Nagoya 466, Japan); Aoki, K. *Gann* 68(6): 715-729; 1977.

To explore the epidemiological and etiological implications of bladder cancer mortality in Japan, national mortality statistics for 1947-1974 were analyzed. The age-adjusted death rate for bladder cancer increased in both sexes prior to the early 1960's, after which the rate leveled off in men and declined in women. Almost identical risks for bladder cancer deaths were noted in men born after 1910 and women born after 1900. The following trends were also identified: an apparent decrease in bladder cancer mortality among the young and an increase in older age groups; a decrease in mean age at death of 5.7 yr in men and 12.7 yr in women; and an unchanged age-specific death rate in men aged < 65 yr and a distinct decline in this rate in women < 65 yr old. There were no definite geographic gradients of the standardized mortality ratio and no apparent clustering of high ratios in prefectures with highly industrialized areas and large cities. These findings are incompatible with the recent remarkable increases in potentially hazardous agents in Japan's environment. Since bladder cancer is one of the few malignancies in which the role of environmental and occupational agents has been shown to be important, the results might indicate the relative importance of inherent host factors and unidentified environmental factors in bladder cancer. This suggestion is supported by the consistent proportion over the years of bladder cancer deaths among deaths from all urinary tract cancers. (47 refs)

78-3569 **Childhood Cancer in Sweden, 1958-1974. I. Incidence and Mortality.** (Eng) Ericsson, J. L. (Central Lab. Clinical Pathology, Univ. Hosp., Univ. Uppsala, Uppsala, Sweden); Karnstrom, L.; Mattsson, B. *Acta Paediatr Scand* 67(4): 425-432; 1978.

Data on the incidence and mortality of childhood cancer in Sweden are presented, based on the 3,797 cases of tumors and tumorlike conditions in children 0-14 yr old reported to the Swedish cancer registry during 1958-1974. During this period, the annual number of cancer cases, deaths, and deaths from cancer (per million) in boys was 142, 1,435, and 93, respectively; the corresponding numbers for girls were 124, 1,066, and 77. Almost half the cancers affected children < 5 yr of age. The lowest incidence occurred at age 7-8 yr, the highest during the first year of life. The most common diagnoses were leukemia and nervous system tumors, both of which constituted 58% of the total. The most common CNS tumors were astrocytomas and related forms, but neuroblastomas predominated in the peripheral nervous system. Teratoma was a comparatively common histopathological diagnosis. The most common leukemias were the acute blast cell and acute lymphatic types. Linear regression analysis of the data for 1958-1974 showed that the increase in incidence rates was significant for boys (2.3%/yr), much less so for girls (0.7%/yr). The major part of the increase in incidence rates was accounted for by nervous system tumors. If these tumors are excluded, the tendency toward an increased occurrence of childhood cancer is abolished. The increase in nervous system tumors was three times higher in boys than in girls. Mortality rates slightly decreased during this period, especially for girls. The decrease in mortality rates was most pronounced for Wilms' tumor and for leukemia in children 0-4 yr of age, a result of improved treatment methods. (13 refs)

78-3570 **Cancer Epidemics in the People's Republic of China.** (Eng) Miller, R. W. (Clinical Epidemiology Branch, Div. Cancer Cause and Prevention, A-521, Landow Building, NCI, NIH, Public Health Service, U.S. Dept. Health, Education and Welfare, Bethesda, MD, 20014). *J Natl Cancer Inst* 60(6): 1195-1203; 1978.

Information on cancer epidemiology gained during a trip by a U.S. Cancer Delegation to four cities and two rural areas of China is reported. Three of four epidemic types of cancer occur regionally and are apparently due to environmental exposures. High incidences of nasopharyngeal carcinoma (NPC) and hepatocellular carcinoma (HCC) occur in the South and esophageal carcinoma (ES) is found in some areas of the North. High incidences of trophoblastic neoplasia occur throughout China. Cases of NPC have also been found in domestic pigs in the same area endemic for human NPC, suggesting that the search for a cause of NPC in man may be narrowed to the small environment of the pig as contrasted with the diverse exposures of man. EC in man was found to be associated with cancers of chicken gullets. In one case of a mass relocation of the human population, the carcinogen causing gullet cancer appeared to have moved with the people to infect the chickens in the new area. HCC was found in a few cirrhotic ducks in an area where the neoplasm occurs excessively in man, but, unlike NPC in pigs and gullet cancer in chickens, no systematic survey of ducks for HCC has been made. Mass surveys have been undertaken in China for cancer detection. In one province, early detection resulting from these surveys has virtually eliminated death from cancer of the uterine cervix in textile workers. (31 refs)

78-3571 **An Outbreak of Pleural Mesothelioma and Chronic Fibrosing Pleurisy in the Village of Karain/Urgup in Anatolia.** (Eng) Baris, Y. I. (Dept. Chest Diseases, Hacettepe Univ. Sch. Medicine, Ankara, Turkey); Sahin, A. A.; Ozesmi, M.; Kerse, I.; Ozen, E.; Kolacan, B.; Altinors, M.; Goktepeli, A. *Thorax* 33(2): 181-192; 1978.

The cause of the 11 deaths from pleural mesothelioma and the 5 cases of fibrosing pleurisy that occurred among the 575 inhabitants of Karain, Turkey, in 1975-76 was investigated. In the previous 5 yr, there had been 25 cases of mesothelioma. There was no definite evidence of a genetic factor; the main occupation of those affected was agriculture. Examination of the physical and economic structure of the village and geological, biological, and chemical analyses of the food, rocks, soil, and water indicated the presence of a few asbestos fibers, 5-7 μm long, in the water. Asbestos fibers were also found in th pleural tissues of 2/5 patients examined. Pleural calcificatio was seen quite frequently, and it was typical of that resultin from asbestos exposure. Inhabitants of neighboring villag were free of mesothelioma. The asbestos fibers may b derived from the wearing down of asbestos-containing rock by the water supply. They are either ingested or inhaled afte the water evaporates and the fibers become airborne. (28 refs

78-3572 **Lung Cancer in Various Chronic Lung Disease** (Rus) Smirnov, E. A. (Dept. Pathoanatom Central District Hosp., Pushkin, Moscow Oblast, USSR *Vopr Onkol* 24(2): 93-95; 1978.

The association of lung cancer with other chronic respirator diseases was evaluated by autopsy examination of 104 patients with lung cancer. Lung cancer was combined wit chronic purulent bronchitis in 26.8% of the cases, wit chronic pneumonia in 12.5%, with fibrous-focal and cirrhoti tuberculosis in 17.3%, with diffuse pneumosclerosis i 11.5%, and with pulmonary emphysema in 9.6%. Centra lung cancer was predominantly associated with chronic purulent bronchitis and pulmonary emphysema (45.5%), peripheral cancer with tuberculosis and chronic pneumoni (56.2%). The patients with chronic purulent bronchitis usually developed poorly differentiated and glandular carcinomas, whereas squamous cell carcinomas were more common in patients with tuberculosis, chronic pneumonia, an diffuse pneumosclerosis. (12 refs)

78-3573 **Relation of Occupations to the Regional Differences of Lung Cancer Mortality in Fukuok Prefecture.** (Eng) Shigematsu, T. (Dept. Public Health Fukuoka Univ. Sch. Medicine, 34 Nanakuma, Nishi-ku Fukuoka 814, Japan); Yamasaki, M. *Jpn J Ind Health* 19(4) 182-188; 1978.

The relationship of occupation to geographical differences i lung cancer patterns was examined in Fukuoka Prefecture Japan. Data for 1971-1973 were taken from previous statistical analyses, cancer registry data, and census reports. In men the standardized mortality rate for lung cancer was 16% higher than that of all Japan; in women, the rate was less tha half that of the men, but 24% higher than the rate for al Japan. An evident clustering of cities and towns with hig death rates was observed in a district that, until 1965, ha been one of the largest coal-mining areas in Japan. Amon 20 cities and boroughs in the prefecture, there were significant correlations between lung cancer incidence and mortality for 1971-1973 and percentages of workers employed i mining and quarrying occupations in every census yr afte World War II. No other occupations showed consistent rela ions to lung cancer rates. The clustering suggests that coal-mining occupations may have a sizeable influence on lung cancer. (19 refs)

78-3574 **A Study of Diet and Breast Cancer.** (Eng) Miller, A. B. (NCIC Epidemiology Unit, Univ. Toronto, McMurrich Building, Toronto, Ontario M5S 1A8, Canada); Kelly, A.; Choi, N. W.; Matthews, V.; Morgan, R. W.; Munan, L.; Burch, J. D.; Feather, J.; Howe, G. R.; Jain, M. *Am J Epidemiol* 107(6): 499-509; 1978.

The effect of dietary factors on the development of breast cancer was studied in four areas of Canada. The study popu-ation, 100 patients with newly diagnosed breast cancer and an equal number of matched controls from each of the areas (total, 400 matched pairs), was administered personal and medical history questionnaires, a detailed dietary history questionnaire, a 24-hr recall for dietary information, and a 4-day diet record. In general, the mean nutrient intake was greater for breast cancer patients than for controls, and the mean nutrient intake for premenopausal breast cancer patients was greater than that for postmenopausal patients. In premenopausal breast cancer patients, total fat, saturated fat, and cholesterol showed risk ratios greater than unity; in postmenopausal patients, only total fat gave risk ratio estimates greater than unity. In all instances, there was little or no indication of a dose-response relationship. In premenopausal patients, when total fat was controlled for saturated fat and vice versa, the risk ratio for total fat became 2.0 and that for saturated fat became 0.4; the risk ratio for cholesterol was reduced when controlled for total fat and saturated fat. The findings on nutrient intake generally support the hypothesis that breast cancer in pre- and postmenopausal women is related to an increased dietary intake of fat. (39 refs)

78-3575 **An Epidemiologic Study of Breast Cancer.** (Eng) Choi, N. W. (Univ. Manitoba, Winnipeg, Manitoba, Canada); Howe, G. R.; Miller, A. B.; Matthews, V.; Morgan, R. W.; Munan, L.; Burch, J. D.; Feather, J.; Jain, M.; Kelly, A. *Am J Epidemiol* 107(6): 510-521; 1978.

An epidemiologic study of suspected risk factors in breast cancer was conducted in four areas of Canada. The study population, 100 patients with newly diagnosed breast cancer and an equal number of matched controls from each of the areas (total, 400 matched pairs), was administered medical and dietary questionnaires. There was evidence of an increased risk of breast cancer in postmenopausal women with younger age at menarche. The study confirmed that the increased risk of breast cancer in postmenopausal women with delay in age of natural menopause is most marked in those who develop breast cancer after the age of 70. However, it failed to confirm that late age at first pregnancy is a risk factor in either pre- or postmenopausal women. For all breast cancer respondents, irrespective of menopausal status, there was an increased frequency of pregnancies of 4 mo duration or less compared with controls; irregularity of periods occured more often in breast cancer patients who were still menstruating than in controls. The latter two findings suggest that women with breast cancer may be less fertile than their controls, tending to support the hypothesis that estrogenic stimulation in the absence of sufficient cyclic progesterone secretion may provide a setting favorable for the development of mammary carcinoma. There was no evidence that increased height or increased wt were risk factors in premenopausal women. Postmenopausal breast cancer patients were on the av taller than controls, but the difference was not significant. There was a significant difference between the wt of postmenopausal breast cancer patients and controls, with the former showing an increased wt both at the time of menopause and at 12 and 6 mo before the interview. This difference in wt was substantial for a group of 13 matched pairs aged 70 yr or more. (31 refs)

78-3576 **Risk Factors of Breast Cancer in Finland.** (Eng) Soini, I. (Detection Centre and Labs. Pirkanmaa Cancer Society, Univ. Tampere, Tampere, Finland). *Int J Epidemiol* 6(4): 365-373; 1977.

Reproductive, hormonal, and other characteristics associated with the risk of breast cancer were examined in a case-control study of 122 cases of breast cancer and 534 controls, all 41 to 60 yr old, in Finland. Finland represents an area of intermediate breast cancer incidence (40.1/100,000), a rate that is low compared with those in the other Nordic countries. Age at first marriage and at the birth of the first child, number of abortions, and parity adjusted for age at first birth were associated with breast cancer risk, whereas lactation was not. Breast cancer risk also showed a positive correlation with anamnestic angina pectoris but not with hypertension or diabetes. The results did not confirm the hypothesis that obesity influences the risk of breast cancer. (19 refs)

78-3577 **Estimates of Composite Risk Factors for Death from Breast Cancer.** (Eng) Davies, D. F. (Dept. Community Medicine, Coll. Medicine, Univ. Tennessee Center Health Sciences, 800 Madison Ave., Memphis, TN, 38163); Torng, A.; Morris, E. B.; Sebes, J. *J Natl Cancer Inst* 61(1): 41-48; 1978.

A method of ranking women according to their weighted composite risks of dying from breast cancer is described. The method uses the device of selecting presumed independent prognostic characteristics, standardizing reported relative risks by conversion to risk factors, and ranking the population of women in order of weighted composite risks. The following prognostic characteristics are employed in the method: family history of breast cancer, pregnancy history, history of benign breast disease, menstrual status, and history of annual breast examinations or recent self-examination of breasts. The proportion of the populations, risk ratios, and risk factors for each prognostic characteristic by mutually exclusive categories and by current 5-yr age groups are tabulated for women between the ages of 40 and 64 yr. For example, in one combination of 45- to 49-yr-old nulliparous women who had no family history of breast cancer, previous benign breast disease, surgical menopause at 40-44 yr of age, and no history of periodic breast examination, the composite risk factor (CRF) is 4.73. For women with these characteristics, the 10-yr risk is the product of the CRF and the av risk of dying from breast cancer in the next 10 yr, or 2,422/100,000. Women with composite risks as high or higher than 4.73 make up 3.1% of the population in the age group but will account for 20.2% of all the age group's breast cancer deaths during the succeeding 10 yr. Among 99.7% of women, the estimated CRF's range between 0.06 and 13.0. The validity and reliability of the method can be checked against data obtained in previous screening programs and in prospective studies that incorporate plans to study concordance of expected and observed data. (40 refs)

78-3578 **Horizontally Transmitted Lymphomas of Syrian Hamsters.** (Eng) Coggin, J. H. (Dept. Microbiology and Immunology, Univ. South Alabama, Mobile, AL, 36688); Thomas, K. V.; Huebner, R. *Fed Proc* 37(7): 2086-2088; 1978.

The occurrence of repeated epizootics in a hamster colony is reported, and attempts made to identify the agent responsible are summarized. The first epizootic was characterized by the development of lymphomas in half a colony of 2,900 male and female LSH, LCG, and LVG hamsters. Tumors were rare before 8 wk of age except among LSH hamsters (13% incidence). Most tumors were noted in 14- to 19-wk-old animals born at the facility or introduced as weanlings. When hamster >8 wk of age were housed in the diseased colony, tumors were less common and they appeared after 25 wk of age. Age matched and sibling hamsters kept 25 miles away remained free of disease. The diseased animals were killed, cleaning and sanitization methods were applied, and a new hamster colony was started. Despite continued sanitization, lymphomas began to appear within 7 mo, predominantly in the intestine. Younger animals introduced into the colony were more susceptible to tumor development than older animals. Tumor incidence in newborn often exceeded 60%/liter. The second colony was killed, the facility again sanitized, and a new colony started. Lymphomas developed in these animals within 4 mo. Other facilities receiving small numbers of hamsters from these infected colonies reported similar epizootics. The tumors were characterized as malignant lymphomas of B-cell origin that invade adjacent tissues and spread to distant sites; death usually resulted within 2-5 wk. A protamine sulfate extract of the tumor induced 50%-80% lymphomas in neonates infected ip. Electron microscopy of the extract did not reveal virus particles. Its infectious capacity could be destroyed by DNase. (3 refs)

78-3579 **High Incidence Area of Cattle Cancer with a Possible Interaction Between an Environmental Carcinogen and a Papilloma Virus.** (Eng) Jarrett, W. F. (Univ. Glasgow Veterinary Sch., Bearsden, Glasgow, England); McNeil, P. E.; Grimshaw, W. T.; Selman, I. E.; McIntyre, W. I. *Nature* 274(5668): 215-217; 1978.

Eighty cases of alimentary cancer in beef cattle from the upland areas of Scotland and northern England were studied. Cattle in these areas are substantially more prone to alimentary cancer than those in the immediately neighboring lowlands. Four types of neoplasms were found: squamous carcinoma and papilloma of the upper tract, and adenoma and adenocarcinoma of the intestine. Squamous carcinomas were found in the lateral dorsum of the tongue, the soft palate and oropharynx, the esophagus, the esophageal groove, and a specific area of the rumen. Papillomas were found in the same sites in 96% of the cattle with squamous carcinomas and in 144/366 of normal cattle from the same region. The number of papillomas per animal was markedly higher among those with cancer than among those without. Several cases showed incontrovertible evidence of the direct transformation of papillomas to carcinomas. Two-thirds of the cattle of known age were aged 12 yr or less. In all cases in which the farms of origin were traced (75%), they contained marginal or hill land infested with bracken. Thirteen percent of the papillomas contained virus that produced typical papillomas after inoculation into the esophagus, palate, or skin. This system provides a means for studying the way in which an oncogenic virus, an environmental chemical (in bracken), and a host cell genome interact to give rise to malignancy. (14 refs)

78-3580 **Epidemiology of Cancer Caused by Occupational Exposure to Harmful Chemicals in East Germany.** (Ger) Braunlich, A. (Zentralinstitut fur Arbeitsmedizin der DDR, Noldnerstrasse 40-42, DDR-1134 Berlin, E. Germany); Enderlein, G.; Haublein, H. G.; Konetzke, G.; Rebohle, E.; Schmidt, P.; Schulz, G.; Thiele, H.; Wallenstein, G. *Z Gesamte Hyg* 24(4): 237-247; 1978.

Epidemiological surveys of occupation-related morbidity and mortality in East Germany are reviewed. According to the National Cancer Registry, approx 40,000 persons die of malignancies each year and nearly 60,000 new cases are reported. Surveys of working populations, obtained by medical tests and routine examinations, revealed a connection between health hazards and harmful chemicals. Various respiratory cancers resulted from occupational exposure to asestos, arsenic, nickel, chromium, polycylic aromatic ompounds and other chemicals. (20 refs)

78-3581 **The Hazards of a Chemical Laboratory Environment--A Study of the Mortality in Two Cohorts of Swedish Chemists.** (Eng) Olin, G. R. (Safety and Health Dept., Royal Inst. Technology, S-100 44, Stockholm, Sweden). *Am Ind Hyg Assoc J* 39(7): 557-562; 1978.

The mortality of 857 chemists educated at two technology institutes in Sweden from 1930 to 1950 and followed until 1974 was studied. There were 93 deaths vs an expected (exp) number of 106, but a significant number of deaths were due to malignant tumors (34 vs 20.8 exp). The increase was accounted for partly by leukemias and malignant lymphomas (8 cases vs 2.6 exp): there were 3 cases of Hodgkin's disease (vs 0.5 exp), 3 lymphosarcomas, and 2 myelogenous leukemias. Prostatic cancer also contributed to the increase (4 cases vs 0.8 exp), and there were three cases of kidney cancer and one of bladder cancer. The frequencies of the other types of tumors did not diverge significantly from the exp number. However, in a separate analysis of the mortality pattern within 24 yr after graduation (in which the class of 1950 was excluded), an increase in brain tumors was found (3 cases vs 0.6 exp). The increased incidence of certain tumors might indicate that there is a relation between these types of tumors and exposure to organic chemicals. (18 refs)

78-3582 **Sunlight as a Risk Factor of Malignant Melanoma of the Skin.** (Eng) Teppo, L. (Finnish Cancer Registry, Liisankatu 21 B, SF-00170 Helsinki 17, Finland); Pakkanen, M.; Hakulinen, T. *Cancer* 41(5): 2018-2027; 1978.

A series of 2,511 malignant melanomas diagnosed in Finland from 1953 to 1975 was analyzed for possible relationships between sunlight and tumor induction. The age-adjusted incidence rate more than doubled for both sexes during the 20-yr study period, reaching $3.5/10^5$ in the early 1970's. The most common tumor sites were the trunk and lower limbs in men (48% and 17%, respectively) and the lower limbs and the trunk in women (56% and 28%, respectively). The age-adjusted incidence rates were higher in urban areas than in rural districts and higher in southern than in northern Finland. However, the north-south differences almost disappeared when the rates were adjusted for the urban/rural population ratio. Thus, the north-south gradient was attributable to urbanization and not to latitude alone. Tumors on the trunk in both sexes and those on the legs in women increased markedly with time; their age-specific rates increased sharply in middle age and then leveled off. Tumors on the head and neck in both sexes and those on the legs of men did not increase with time; the risk of these tumors was low in middle age but continuous throughout life. The increased melanoma risk with time is in accord with cohort analyses, which show that successive generations born between the late 1800's and 1930-1940 have been exposed increasingly to factors associated with melanoma development. The anatomical distribution of the melanomas in this series suggests that sunlight is not the only important risk factor. (21 refs)

78-3583 **Theoretical Aspects of Radiation Carcinogenesis: Cell Survival Dependent Dose-Rate Effects.** (Eng) Wells, J. (Central Electricity Generating Board, Berkeley Nuclear Lab., Berkeley, Gloucestershire, GL13 9PB, England). *J Institution Nuclear Engineers* 19(3): 89-97; 1978.

A cellular response function (CRF) for radiation carcinogenesis is presented and used in an illustrative study of cell survival-dependent dose rate effects, with particular reference to point source β-particle emitters. Parameters for a CRF for carcinogenesis are derived from human, animal, and in vitro data. The CRF is integrated to make predictions about the macroscopic response of organs and tissures to radiation. Previous mathematical methodology is considered in terms of a more general form of CRF that incorporates parameters that can be associated readily with all major variables. Such a function can be developed from established radiobiological data and can, in turn, be used as a planning criterion for experiments on cell transformation in vitro and tumor induction in animals. (19 refs)

78-3584 **Point of View--Misleading Reports on Japanese Incidence of Prostatic Cancer.** (Eng) Ravich, A. (1135-103rd St., Miami Beach, FL, 33154). *Urology* 11(5): 542; 1978.

Differences in the prostatic cancer incidence in Japan (2%) and the US (20%) are partially the result of the method of reporting: in the US, the number of cases is compared with the number of prostatectomies, but in Japan the number of cases is compared with the number of male patients in the urology clinic. There is small number of prostatectomies in Japan, the result of reluctance of patients to go to a urologist. It is suggested that prostatic cancer is a viral venereal disease involving the prostate and smegma. (3 refs)

MISCELLANEOUS

78-3585 **Characterization of a Unique Cell Line (LAZ 221) from Human Acute Lymphocytic ("Null" Cell) Leukemia.** (Eng) Lazarus, H. (Sidney Farber Cancer Inst., Harvard Medical Sch., Boston, MA, 02115); Barell, E. F.; Krishan, A.; Livingston, D. M.; Harris, K.; Schlossman, S. F.; Chess, L. *Cancer Res* 38(5): 1362-1367; 1978.

The establishment of a cell line, LAZ 221, from a 24-yr-old woman with acute lymphocytic leukemia of the null cell type is reported. After 3 mo, the cultures attained a doubling time of ≥4 days and had max viable cell densities of 4-5 x 10^6 cells/ml. Agar culture indicated that the line was free of *Mycoplasma* after 18 mo in culture. The cell line does not possess the Epstein-Barr virus nuclear antigen, and it has a karyotype of 45,XX,-9,-12,+t(9q12q). Both the cultured cells and the patient's uncultured blast cells shared the same phenotypic markers, and they both lacked T- and B-cell markers. They failed to form sheep RBC rosettes, they did not react with T-cell-specific antisera (TH_1-, HTL-), they did not form rosettes with RBC sensitized with antibody and complement, and they were surface immunoglobulin negative. However, they did possess a histocompatibility antigen (HLA-D)-related glycoprotein complex of 23,000-30,000 daltons, which was shown to have properties of an Ia-like antigen. This cell line is thus representative of about 75% of all human acute lymphocytic leukemias. (24 refs)

78-3586 **Growth Promoting and Inhibitory Activities of 3T3 and Other Cell Lines for Thiol-dependent Lymphoma Cells In Vitro.** (Eng) Tanapat, P. (Dept. Pathology, State Univ. New York, Downstate Medical Center, Brooklyn, NY, 11203); Gaetjens, E.; Broome, J. D. *Proc Soc Exp Biol Med* 157(3): 517-521; 1978.

The effects of various 3T3 cells (simian virus 40-transformed Swiss, spontaneously transformed BALB/c, Swiss, BALB/c) on the growth of the thiol-dependent lymphoma line L1210(V) were determined. All cells, regardless of whether they showed contact inhibition or were transformed, supported the growth of L1210(V) cells. However, these supporting cells do not condition the medium permanently. At high cell densities, growth promotion was diminished. These results were compared to other findings with macrophage cultures that had previously been shown to support the growth of mouse lymphoma cells. Macrophages produced approx the same degree of L1210(V) growth promotion as did the other lines, but as the cell density of the macrophages increased, lymphoma cell growth became increasingly more rapid (2.8 divisions at 2 x 10^6 cells). The mechanisms of this growth promotion were then studied further. Supernatants of macrophage cultures that had been able to sustain L1210(V growth were unable to do so. Once mixed cultures of macrophages and L1210(V) cells were established, however, lymphoma cell growth was supported. Supplements of fresh medium every 48 hr, to reduce the lymphoma cell density to its original size, resulted in no increase in cell number unless thiol was added. Diffusion chamber experiments indicated that macrophages and 3T3 cells, but not supernatants from macrophage cultures, supported lymphoma growth. These experiments indicate that growth promotion is mediated humorally. Studies with the L1210(A) thiol-independent subline indicated that the growth failure of L1210(V) in supernatant medium was distinct from the thiol dependency. Like L1210(V) cells, this subline failed to grow with 3T3 cells at high density or with the 3T3 culture supernatant. It is suggested that a nondialyzable inhibitor of lymphoma cell growth is produced by 3T3 cells. (9 refs)

78-3587 **Isolation of a Bone-resorptive Factor from Human Cancer Ascites Fluid.** (Eng) Nimberg, R. B. (Dept. Biochemistry, Boston Univ. Sch. Medicine, Boston, MA, 02118); Humphries, D. E.; Lloyd, W. S.; Badger, A. M.; Cooperband, S. R.; Wells, H.; Schmid, K. *Cancer Res* 38(7): 1983-1989; 1978.

A protein fraction that induces the resorption of bone explants in organ culture was isolated from the ascitic fluid of patients with advanced cancer metastatic to the peritoneal cavity who had not yet received any chemotherapy or radiotherapy. Partial purification was achieved by gel filtration, affinity chromatography, and ion-exchange chromatography. The isolated fraction, the components of which have an apparent mol wt of 60,000, was found to be heterogeneous by disk gel electrophoresis and to be composed primarily of proteins with relatively acidic electrophoretic properties. The specific bone-resorptive activity of this protein fraction was greatly increased over that of the unfractionated starting material, but the activity was completely destroyed by incubation with pronase and by heating. Immunoassay and extraction procedures showed that the bone-resorptive action was not due to the presence of parathyroid hormone, prostaglandin E_2, or vitamin D-like sterols. In parallel experiments with the supernatants of phytohemagglutinin-stimulated normal human peripheral WBC, a protein fraction with a mol wt of 60,000, which resembled the resorptive fraction isolated from cancer ascites fluid and which contained significant bone-resorptive activity, was also partially purified. If the bone-resorptive factor in tumor ascites fluid is involved in the production of tumor-related osteolytic lesions and tumor-related hypercalcemia, the purification and chemical ıd biological characterization of this protein could be a maır step toward understanding the mechanism by which tuıors destroy bone and alter calcium metabolism. (28 refs)

8-3588 **Production of a Corpus Luteum Angiogenic Factor Responsible for Proliferation of Capilaries and Neovascularization of the Corpus Luteum.** (Eng) ɔospodarowicz, D. (Cancer Res. Inst., Univ. California, San ⁼rancisco, CA, 94143); Thakral, K. K. *Proc Natl Acad Sci USA* 75(2): 847-851; 1978.

The abilities of ovarian corpus luteum and of follicles to inluce neovascularization were compared by implanting these issues in rabbit cornea, a transparent, avascular substratum n which the rates of new vessel formation and the parts played by the host and the ovarian implant can be easiliy studied. The corpus luteum was capable of inducing neovascularization but the follicles were not. This is in agreement with the in vivo situation, in which active capillary proliferation is observed only with corpus luteum, whereas follicles are an avascular structure. Corpus luteum crude extracts were potent stimulators of the initation of DNA synthesis in BALB/c 3T3 cells and in bovine vascular endothelial cells. Follicular extracts were inactive. This supports the hypothesis that corpora lutea can secrete an angiogenic factor, corpus luteum angiogenic factor (CLAF). Thus, although the initial stimulus for the neovascularization is probably the increased demand for oxygen of the luteal cells caused by their high metabolic activity, the factor involved in inducing the proliferation of capillaries is a mitogenic factor (CLAF) produced by the corpus luteum. (21 refs)

78-3589 **Density-dependent Mitosis in the Walker 256 Carcinoma and the Influence of Host Age on Growth.** (Eng) Bellamy, D. (Dept. Zoology, Univ. College, Cardiff CF1 1XL, Wales); Hinsull, S. M. *Eur J Cancer* 14(7): 747-751; 1978.

The Walker 256 carcinoma was tested for density dependence of cell division, and the effect of host age on growth regulation was examined. Tumor tissue (6-mg fragment) from 20-wk-old donor rats bearing a solid, sc Walker 256 carcinoma was inserted sc into the middorsal region of 20- or 120-wk old male rats of an inbred WAB substrain. Colchicine was administered ip 4 hr before the animals were killed (3-10 days following tumor implantation), and the tumor tissue was removed. There was no difference in tumor size between the two age groups until 6 days after transplantation. Thereafter, the tumor growth rate in the older group was lower than that in the 20-wk-old animals. Overall tumor cell proliferation in 120-wk-old animals was much lower than that observed in 20-wk-old hosts. The magnitude of this difference increased from 100% 3 days after transplantation to 300% at 6 days. Therefore, a significant difference in tumor cell proliferation between the two groups occurred before any difference in tumor wt became apparent. The mitotic rate declined with increasing cell density, and it was more dependent upon cell density in tumors of old hosts. The mitotic pattern of tumors of old hosts was closer to that observed in normal tissue, implying a better regulation. (21 refs)

78-3590 **Collagenolytic Activity and Spreading Mode of Human Stomach Cancer.** (Jpn) Itoh, K. (First Dept. Surgery, Okayama Univ., Medical Sch., Shikada-cho, Okayama 700, Japan). *Okayama Igaku Zasshi* 89(9/10): 1101-1117; 1977.

The degradation and resorption of collagen in malignant gastric tumors were investigated by the Gross and Lapiere method, which involves tissue incubation with an animal collagenolytic enzyme that acts at neutral pH and physiologic body temperature. Histological observations were performed simultaneously to study the relationship between tumor collagenolytic activity and morphology. The collagenolytic activity was significantly higher in gastric cancer tissue than noncancerous gastric tissue. In the cancers, the collagenolytic activity was elevated at the spreading front. Although not as high as in the cancer tissue, the collagenolytic activity of the surrounding tissues was higher than normal. Well-differentiated adenocarcinomas showed relatively high collagenolytic activity in their centers and spreading fronts. In poorly differentiated adenocarcinomas, the activity was low in the center, but it gradually increased in the spreading front. There was no difference in collagenolytic activity between the center and spreading fronts of massive, continuous-type lesions; in the nonmassive interspersed and nonmassive continuous types, however, there was a great difference in activity between the spreading front and the center of the lesion. Borrmann type I tumors showed the characteristic distribution of collagenase activity; ie, high in the lesion but low in the surrounding region. In contrast, in Borrmann type IV tumors it was elevated throughout the stomach. (37 refs)

78-3591 **Collagenase in Malignant Tumors. 2. Collagenolytic Activity and Its Relation to the Development of Human Stomach Cancer.** (Jpn) Mimura, T. (First Dept. Surgery, Okayama Univ., Medical Sch., Schikada-cho, Okayama 700, Japan). *Okayama Igaku Zasshi* 89(9/10): 1165-1176; 1977.

The collagenolytic activity of 38 human stomach cancers was measured by the culture methods of Gross and Lapiere, and histological observations were made simultaneously to examine the relationship between this activity and the morphological pattern of the cancer. Collagenolytic activity was significantly higher in gastric cancer tissues than in normal stomach tissues. The strongest activity was observed in the spreading front and the center of the gastric cancers. In the surrounding tissues, the activity was only slightly higher than normal. The more poorly differentiated the tumor, the higher the collagenolytic activity; and in poorly differentiated adenocarcinomas, the activity was stronger in medullary than in scirrhous tumors. Borrman Type IV cancer showed elevated collagenolytic activity throughout the lesion. In contrast, this activity was weak in 0- and 5-type cancers. In the superficial spreading type of early gastric cancer, the collagenolytic activity was associated with the horizontal direction of cancer development. (20 refs)

78-3592 **Isolation and Partial Purification of Cytochrome P-450 from Uninduced Rat Liver.** (Eng) Dialameh, G. H. (Dept. Biochemistry, Faculty Basic Medical Sciences, Univ. Tehran, Tehran, Iran). *Biochem Biophys Res Commun* 81(1): 19-23; 1978.

The isolation of cytochrome P-450 from uninduced male rat liver is reported. The specific level of cytochrome P-450 was 9.6 nanomoles/mg protein; it was stable in 20% glycerol, and it could be stored for 2 wk at -20 C without spectral changes. The cytochrome catalyzed the NADPH-dependent hydroxylation of benzo(a)pyrene when it was mixed with an NADPH-cytochrome c reductase preparation and purified microsomal lipid. (21 refs)

78-3593 **Dissociation of Plasminogen Activator from the Transformed Phenotype in a 5-Bromodeoxyuridine Dependent Mutant of Syrian Hamster Melanoma Cells.** (Eng) Rosenthal, S. L. (Div. Human Genetics, Children's Hosp. Medical Center, Boston, MA, 02115); Zucker, D.; Davidson, R. L. *J Cell Physiol* 95(3): 275-285; 1978.

The relationship between plasminogen activator levels and the expression of the transformed phenotype was studied in a 5-bromodeoxyuridine (BUdR)-dependent mutant of Syrian hamster melanoma cells. The BUdR-dependent cells resemble transformed cells when grown in the presence of BUdR, untransformed cells when grown in its absence. The BUdR-dependent cells released significant levels of plasminogen activator only when cultured in the absence of BUdR. In the presence of BUdR, the release of plasminogen activator by the dependent cells was suppressed, and the decreased level of plasminogen activator released in the presence of BUdR appeared to be due to decreased production of active enzyme. Growth tests indicated that when BUdR-dependent cells were attached to a substrate, BUdR was required to attain high densities. Furthermore, the cells were able to grow well in soft agar only in the presence of BUdR. These findings suggest that the production and release of high levels of plasminogen activator are not related to expression of the tran formed phenotype in the BUdR-dependent cells. Cells cu tured in medium containing dog serum as a plasminoge source exhibited morphological alteration, but only in th presence of BUdR. The morphological response of the cel to dog serum resembled that previously observed wit virus-transformed cells. In the BUdR-dependent cells, th morphological response to dog serum appeared to be correla ed with the release of plasminogen activator but separate from other transformed characteristics. (21 refs)

78-3594 **Genetic Transcription of Human Leukem Cells.** (Eng) Sawada, H. (Dept. Internal Med cine, Faculty Medicine, Kyoto Univ., Sakyo-ku, Kyoto 60 Japan); Tashima, M. *Acta Haematol Jpn* 40(6): 1117-113 1977.

Chromatins isolated from human leukemic WBC were ch racterized with respect to chemical composition, therm denaturation, template activity, transcription products DNA-RNA hybridization, and the amount of unique DN sequences transcribed. Chromatins from patients with acu lymphoblastic leukemia, acute myeloblastic leukemia, lymphosarcoma had higher thermal denaturation values an contained more nonhistone chromosomal protein tha chromatins from patients with chronic lymphocytic leukem (CLL) or normal subjects. The acute leukemia chromati also had higher template activity than CLL and normal lyn phocyte chromatins. The repetitive DNA transcripts fro CLL and normal lymphocyte chromatin templates were e sentially the same. In hybridization experiments with uniq ^{3}H-DNA, the RNA's from all leukemic WBC had essential the same saturation value (2.5%), indicating that the cel transcribed a similar amount of the unique genome. (28 ref

78-3595 **Stimulation of Thymidine Incorporation Mouse Liver and Biliary Tract Epithelium Lithocholate and Deoxycholate.** (Eng) Bagheri, S. A. (Liv Study Unit, Dept. Medicine, Univ. Chicago, Chicago, IL Bolt, M. G.; Boyer, J. L.; Palmer, R. H. *Gastroenterolo* 74(2, part 1): 188-192; 1978.

The effect of a single po dose of various bile salts on thym dine (TdR) incorporation in female white mouse (CF1) liv and biliary tract epithelium was investigated. The time cour of TdR incorporation after a single 1-mg/kg dose of sodiu lithocholate revealed a marked increase in incorporation in biliary tract DNA at 22-28 hr, but no increase in incorpor tion into liver DNA until 36 hr. For both tissues, the thres old dose for sodium lithocholate was approx 12.5 mg. T results for the same doses of other bile salts indicated th deoxycholate induced more incorporation into biliary tra and liver DNA than did lithocholate or cholate. Chenodeox

olate did not enhance incorporation in either tissue. Fol-
wing the administration of 1 mg/kg lithocholate, liver tis-
e showed areas of focal necrosis randomly distributed in
e parenchyma. Neither deoxycholate- nor cholate-treated
iimals had necrotic areas, but there was an increase in the
ımber of hepatocytes undergoing mitosis. Chenodeoxycho-
te, ursodeoxycholate, and hyodeoxycholate had no effect.
is suggested that these bile acid-induced changes could be
'importance in hepatic, biliary, or intestinal carcinogenesis.

8-3596 **Repair of Alkylated DNA in Chinese Hamster
Cells Measured by Loss of Enzyme-sensitive
ites in Isolated DNA.** (Eng) Shackleton, J. (Inst. Cancer
.es., Pollards Wood Res. Station, Nightingales Lane, Bucks,
'halfont St. Giles, England); Roberts, J. J. *Biochem Biophys
'es Commun* 81(4): 1168-1174; 1978.

procedure was developed for measuring the induction and
epair of alkylation-induced enzyme-sensitive damage in
)NA in Chinese hamster cells. Lesions induced in Chinese
amster cell DNA by dimethyl sulfate (DMS) were recog-
ized by an enzyme present in crude extracts of *Micrococcus
iteus*. These enzyme-sensitive sites on the alkylated DNA
'ere lost with a half-life of 2.4 hr during the first 6 hr after
eatment, and they disappeared completely by 24 hr. The
umber of the enzyme-sensitive sites in methylated DNA
10% of the estimated 100 methylation sites in a DNA
f 10^8 daltons), their rate of loss, and their heat lability
re consistent with the majority being 3-methyladenine
dducts of DNA. (21 refs)

8-3597 **Detection of Inapparent Nodule-transformed
Cells in the Mammary Gland Tissues of Virgin
'emale BALB/cfC3H Mice.** (Eng) DeOme, K. B. (Dept.
'oology, Univ. California, Berkeley, CA, 94720); Miyamoto,
1. J.; Osborn, R. C.; Guzman, R. C.; Lum, K. *Cancer Res*
8(7): 2103-2111; 1978.

napparent nodule-transformed cells were recovered from
orphologically normal mammary tissue from virgin female
ALB/cfC3H/Crgl (mouse mammary tumor-positive) mice
efore the appearance of hyperplastic alveolar nodules
HAN) or tumors by a cell-dissociation technique. Mammary
issues were dissociated by collagenase (0.1%), hyaluronidase
).1%), and pronase (1.25%). Aliquots of 10^5 viable cells in
.01 ml medium were injected into the gland-free mammary
at pads of 3-wk-old female syngeneic mice. After 10 wk, the
utgrowths were examined and classified as ductal, HAN,
ımorous, or combinations of these types. The presence of
IAN outgrowths indicated the presence of nodule-trans-
ormed cells in the donor mammary tissues. Nodule-trans-
ormed cells were recovered from 2-mo-old donors, and the
umber of HAN outgrowths increased with donor age. Overt
HAN and tumors did not appear in virgin female BALB/cfC3H/Crgl mice $<$8-9 mo of age. The data suggest that inapparent nodule-transformed cells were present long before the appearance of overt HAN or tumors and that the numbers of transformed cells increased with donor age. (25 refs)

78-3598 **Suppression by *Nocardia Rubra* Cell Wall Skeleton of Mammary DNA Synthesis, Plasma Prolactin Level, and Spontaneous Mammary Tumorigenesis in Mice.** (Eng) Nagasawa, H. (Pharmacology Div., Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-ku, Tokyo 104, Japan); Yanai, R.; Azuma, I. *Cancer Res* 38(7): 2160-2162; 1978.

The effects of the cell wall skeleton (CWS) of *Nocardia rubra* on mammary gland DNA synthesis, plasma prolactin levels, and spontaneous mammary tumorigenesis in female SHN mice were investigated. The mice received sc injections of 100 μg CWS every 7 days between 2 and 12 mo of age. Whereas mammary tumors began to appear before 5 mo of age in control mice, they did not appear until 7 mo in CWS-treated mice. The incidence increased with age in both groups, but it was significantly lower in the CWS-treated mice than in controls throughout the experiment except at 9 and 12 mo of age. The onset age of mammary tumors was significantly higher in SWS-treated mice (8.9 ± 0.4 mo) than in controls (7.2 ± 0.2 mo). Treatment of mice with CWS also reduced normal mammary gland DNA synthesis and prolactin levels in the circulation; both of these parameters are primary factors in mammary tumorigenesis. The fact that there was no difference between CWS-treated mice and controls in terms of mammary tumor incidence at 12 mo of age infers that the limit of inhibitory activity of CWS on spontaneous mammary tumorigenesis in mice is largely controlled by genetic factors. (20 refs)

Subject Index:

Abnormalities
- Estradiol
  - Vagina, 78-3555
- 4,4′-Stilbenediol, α,α′-Diethyl-
  - Genital Tract, Mouse, 78-3237

Abortion
- Breast Neoplasms
  - Epidemiology, Finland, 78-3576

Acetamide, *N*-(Acetyloxy)-*N*-fluoren-2-yl-
- Adenosine Cyclic 3′,5′ Monophosphate
  - Cell Transformation, Neoplastic, 78-3130
- Adenyl Cyclase
  - Isoproterenol, 78-3130
  - Norepinephrine, 78-3130
  - Prostaglandins E, 78-3130
  - Sodium Fluoride, 78-3130
- Aryl Hydrocarbon Hydroxylases
  - Metabolism, Rat, 78-3132
- 7,8-Benzoflavone
  - Metabolism, Rat, 78-3132
- Cell Transformation, Neoplastic
  - Embryo, Rat, 78-3131
  - Ultrastructural Study, 78-3131
- Cholanthrene, 3-Methyl-
  - Ames Test, 78-3132
- Cysteine
  - Ames Test, 78-3076
- DNA Repair
  - Age Factors, 78-3198
  - Blood Pressure, 78-3198
- DNA Replication
  - Dose-Response Study, 78-3128
- DNA, Single Stranded
  - DNA Replication, 78-3128
- Granulocytes
  - DNA Repair, 78-3198
- Liver
  - Metabolism, Rat, 78-3132
- Liver Neoplasms
  - Precancerous Conditions, 78-3523
- Lymphocytes
  - Chromosome Aberrations, 78-3198
  - DNA Repair, 78-3198
- Phosphoric Acid, Diethyl-, *p*-Nitrophenyl Ester
  - Ames Test, 78-3132

Acetamide, *N*-(Acetyloxy)-*N*-fluoren-3-yl-
- Cell Transformation, Neoplastic
  - Embryo, Rat, 78-3131
  - Ultrastructural Study, 78-3131

Acetamide, *N*-(Acetyloxy)-*N*-(4-(2-phenylethenyl)phenyl)-
- Acetone
  - Uracil Derivative, 78-3176
- Cytosine, 1-Methyl-
  - Uracil Derivative, 78-3176

Acetamide, *N*-Fluoren-2-yl-
- Aryl Hydrocarbon Hydroxylases
  - Metabolism, Rat, 78-3132
- 7,8-Benzoflavone
  - Metabolism, Rat, 78-3132
- Carcinogenic Potential
  - Sebaceous Gland Suppression Test, 78-3129

Acetamide, *N*-Fluoren-2-yl- (cont'd)
- Cholanthrene, 3-Methyl-
  - Ames Test, 78-3132
- Chromatids
  - Mutagenic Activity, 78-3134
- Genetics

GENERAL INFORMATION

ARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis rticles collected from the current major biomedical sources of world literature. This service is provided by the ational Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, nder Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and 'elfare. Published and distributed by the Franklin Institute Press^{SM}.

SUBSCRIPTIONS

'or sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 15, consisting of 12 ıonthly issues and a cumulative index is $75.00, Domestic and $90.00, Foreign. Check should be made payable to The 'ranklin Institute Press.

laruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS .BSTRACTS in Japan.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 15, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations.*

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)
ACTH	adrenocorticotropic hormone
ADP	adenosine diphosphate
AMP	adenosine monophosphate
ATP	adenosine triphosphate
approx	approximately
av	average
BCG	bacillus Calmette-Guerin
bid	twice daily
C	degree(s) centigrade
cal	calorie(s)
kcal	kilocalorie(s)
cc	cubic centimeter(s)
Ci	curie(s)
mCi	millicurie(s)
μCi	microcurie(s)
cm	centimeter(s)
CNS	central nervous system
cpm	counts per minute
DNA	deoxyribonucleic acid
ED_{50}	median effective dose
EDTA	ethylenediamine tetraacetic acid
g	gram(s)
kg	kilogram(s)
mg	milligram(s)
μg	microgram(s)
Hb	hemoglobin
hr	hour(s)
ia	intra-arterial
id	intradermal
IgA	Immunoglobulin A
IgB	Immunoglobulin B
IgG	Immunoglobulin G
IgM	Immunoglobulin M
ILS	increased life span
im	intramuscular
ip	intraperitoneal
IU	International Unit(s)
iv	intravenous
Km	Michaelis constant
LD	lethal dose
LD_{50}	median lethal dose
M	molar
μM	micromolar
mOsm	milliosmolar
max	maximum
mEq	milliequivalent(s)
min	minute(s)
ml	milliliter(s)
μl	microliter(s)
mm	millimeter(s)
mo	month(s)
mol wt	molecular weight
N	normal concentration
NAD	nicotinamide adenine dinucleotide
NADH	reduced nicotinamide adenine dinucleotide
NADP	nicotinamide adenine dinucleotidephosphate
NADPH	reduced nicotinamide adenine dinucleotidephosphate
NCI	National Cancer Institute
NIH	National Institutes of Health

wt	weight
X	times
yr	year(s)

8-3601 **Possibilities and Limitations of the Evaluation of Chemical Carcinogenesis.** (Ger) Schramm, T. Zentralinstitut fur Krebsforschung der AdW der DDR, Beran, E. Germany); Teichmann, B. *Sitzungsber Akad Wiss DDR* (11 N): 13-17; 1978.

'he carcinogenicity of some compounds varies from species o species, making extrapolation from animals to humans dificult. In addition, cocarcinogenic, synergistic, and protective actors usually exist in the human environment, making exrapolation even more difficult. An improved reporting sysem that links human cancer incidence with carcinogen expoure is needed. (8 refs.)

'8-3602 **Proper Perspectives in Extrapolation of Experimental Carcinogenesis Data to Humans.** (Eng) Craybill, H. F. (NCI, Bethesda, MD, 20014). *Food Technolo-y* 32(8): 62-64; 1978.

'he question whether data from animal studies are reliable redictions of carcinogenic events to humans is explored. All hemicals that have been shown to be carcinogenic to humans ave been ultimately verified as carcinogens in animals except enzene and arsenic (As). These chemicals are either noncarinogenic to experimental animals or there is no appropriate nimal model or, in the case of As, the proper compound emains to be tested. Several accepted predictive factors, inluding reproducibility of animal tests in various species and trains with multiple confirmations in different laboratories, lose-dependent increase of tumor incidence, experimental loses approximating human exposure, are listed. If animal lose-response data are augmented by significant biochemical, harmacokinetic data, the probability of translating events o humans becomes more meaningful. Also listed are some f the limiting factors in extrapolation, such as inappropriate oute of administration; improper test species and strains; ole of diet, nutrition, and diet contaminants; and contaminants in test chemicals. Animal data are presumptive evilence that should imply some element of concern as an inlicator test system. Epidemiological studies can provide lirect evidence, but these investigations may not reveal actual exposures and they may only provide observed effects long fter exposure. (8 refs.)

'8-3603 **Criteria for Selecting Chemical Compounds for ,Carcinogenicity Testing: An Essay.** (Eng) Aros, J. C. (Seamen's Memorial Res. Lab., U.S. Public Health Service Hosp., 210 State St., New Orleans, LA, 70118). *J Environ Pathol Toxicol* 1(4): 433-458; 1978.

Criteria for selecting suspected chemicals for carcinogenicity testing are described. The structural criteria are based on analogies with known types of chemical carcinogens. Operational criteria, which are complementary to structural criteria, are the set of biofunctional capabilities in organic compounds likely to bring about or lead to ultimately inheritable alterations in cellular synthetic templates. The 'guilt by association' criterion states that if a compound belongs to a chemical class that includes many potent and multitarget carcinogens, it should be assayed under more stringent conditions than the standard conditions of bioassay testing. The 'after the fact' criterion uses prior human epidemiological indications as the basis for selecting chemical agents for carcinogenicity testing. In determining the significance of bioassay data obtained by testing individual compounds, the possible complicating effects of other environmental carcinogens and noncarcinogens, viral agents, and factors such as nutrition, age, and stress should be considered. A flexible approach is needed for the establishment of standards and guidelines applicable to categories and types of chemical agents rather than individual compounds. (104 refs.)

78-3604 **Quantitative Theories of Oncogenesis.** (Eng) Whittemore, A. S. (Hunter Coll., City Univ. New York, New York, NY). *Adv Cancer Res* 27: 55-88; 1978.

Several quantitative theories of the origin of neoplasms are examined both qualitatively and quantitatively, by comparing their predictions with epidemiological and experimental observations. These theories, which relate the frequency and time of occurrence of tumors to the temporal and spatial distribution of oncogenic exposure, are the single-stage theory of Iverson and Arley, the multicell theory of Fisher and Hollomon, the multistage theory with negligible cell loss, the multistage theory with nonnegligible cell loss, and the multistage theory with proliferative advantage of intermediate cells (including variations by Armitage and Doll and by Fisher). Because these theories do not postulate alteration of tumor growth rates by carcinogenic exposure, none of them can account for the tumor regression that occurs after termination of promoter painting or the lack of tumors that accompanies short exposures to high doses of promoter. Therefore, the single stage or multistage theory with variation in transformed cell types was developed that generalizes many of the previous theories and, by including variable tumor growth that may be affected by exposure, provides a framework for examining initiation-promotion data. Most of these theories ignore the crucial distinction between benign and malignant tumors and none include the possibility of cell repair or the action of the host's immune system. However, despite their limitations, the single and multistage theories provide a flexible, broad, and biologically plausible framework in which to examine the gross behavior of oncogenesis data. (41 refs.)

78-3605 **Some Current Perspectives on Chemical Carcinogenesis in Humans and Experimental Animals: Presidential Address.** (Eng) Miller, E. C. (McArdle Lab. Cancer Res., Univ. Wisconsin Medical Center, Madison, WI, 53706). *Cancer Res* 38(6): 1479-1496; 1978.

Current concepts of chemical carcinogenesis in humans and experimental animals are reviewed. Topics discussed include: tumor induction as a multistage phenomenon; electrophilicity as a common property of ultimate carcinogens; examples of the metabolic activation and reactivity of chemical carcinogens; possible molecular mechanisms of chemical carcinogenesis; prevention of the promotion of initiated cells; and extrapolation of the basic knowledge of chemical carcinogenesis to the prevention of human cancer. Regarding the molecular mechanism of carcinogenesis, examples are cited to illustrate that metabolic activation is an essential step in the induction of neoplasia by most chemical carcinogens. The electrophilic ultimate carcinogens can react, probably more or less indiscriminately, with a number of nucleophilic sites in DNA, RNA, and proteins. Thus, the strong electrophilic nature of ultimate carcinogens is consistent with both genetic and epigenetic mechanisms of carcinogenesis or with mechanisms that include both genetic and epigenetic events. These mechanisms may or may not involve the expression of oncogenic viral information. Chemicals generally recognized as being carcinogens in humans include: 2-naphthylamine, benzidine (4,4′-diaminobiphenyl), 4-aminobiphenyl, 4-nitrobiphenyl, bis(chloromethyl) ether, bis(2-chloroethyl) sulfide, vinyl chloride, certain soots, tars, and oils, chromium compounds, nickel compounds, asbestos, cigarette smoke, betel nut or tobacco quids, N,N-bis(2-chloroethyl)-2-naphthylamine, and diethylstilbestrol. (235 refs.)

78-3606 **Fundamental Carcinogenic Processes and Their Implications for Low-Dose Risk Assessment (Letter to Editor).** (Eng) Crump, K. (Dept. Mathematics and Statistics, Louisiana Technocological Univ., Ruston, LA, 71272). *Cancer Res* 38(6): 1836-1839; 1978.

Differences in opinion concerning the validity and conservatism of the Mantel-Bryan approach to estimating the low-dose risk for carcinogens are discussed. It is emphasized that the arbitrariness and poor fit to date of the Mantel-Bryan probit model are conceded properties of the procedure and that the model was never claimed to provide a fit to the data. Rather, it was only claimed to provide an upper limit, under stated assumptions, to the true dose response at low dosage levels, with the plausible exception for one-hit models being indicated. (25 refs.)

78-3607 **Suggested Procedures for Reducing the Pathology Workload in a Carcinogen Bioassay Program, Part II: Incorporating Blind Pathology Techniques and Analysis for Animals with Tumors.** (Eng) Fears, T. R. (Field Studies and Statistics Program, NCI, NIH, Bethesda, MD); Douglas, J. F. *J Environ Pathol Toxicol* 1(3): 211-222; 1978.

The pathology workload in a carcinogen bioassay program can be reduced by procedures that incorporate blind pathology and recover the total tumor aspect. A procedure that incorporates the total tumor concept and results in pathology workload savings (PWS) of 17%-25% involves four steps: (1) examine microscopically (ExM) only common tumor sites in all of the control animal; (2) ExM all tissue sites in the treated animals; (3) in control animals, ExM all additional tissues for which a positive result is possible in at least one of the treatment groups; (4) ExM all remaining tissues of any control group for which a significant increase in total group tumors is still possible. In step 4, if any Fisher exact test for total tumors is positive and the increase cannot be attributed to an effect on one tissue or system, all tissues of the remaining controls are examined. Blind pathology can be incorporated by using either one of two procedures. One, which results in a PWS of 11%-33%, involves the following two steps: (1) ExM all tissue sites of all treatment animals; (2) examine in all controls and all treated animals those tissues for which a total of five or more animals in at least one treatment group had a tumor. In step 2, the slides are grouped by animals, and the groups are given to the pathologist in random order without being labeled as to treatment. The other procedure for incorporating blind pathology, which results in a PWS of 22%-58%, involves the following four steps: (1) identify treatment animals with a lump or bump at gross pathology; (2) ExM all tissues of animals in a random sample from the lump or bump section of each treatment group; (3) in the remaining treatment animals, examine all tissues in which a tumor was found in any of the sampled animals; (4) in all controls and all treated animals, examine those tissues for which a total of five or more animals of a treatment group had a tumor. In step 4, the slides are grouped by animals, and the groups are given to the pathologist in random order without being labeled as to treatment. (7 refs.)

78-3608 **Current Concepts on Mechanisms of Chemical Carcinogenesis.** (Eng) Weinstein, I. B. (Inst. Cancer Res., Columbia Univ., Coll. Physicians and Surgeons, Health Sciences Center Building, 701 W. 168th St., New York, NY, 10032). *Bull NY Acad Med* 54(4): 366-383; 1978.

Some of the mechanisms of chemical carcinogenesis are reviewed. There is a wide diversity of neoplastic agents, both natural and manmade, that cause cancer. Not all of these agents, however, are carcinogenic in themselves: they require metabolic activation. The metabolites generally act by modifying the nucleic acid composition, and if the defect is not excised, a mutation will occur that can be passed to progeny cells. The role of tumor promotors and cofactors in carcinogenesis is also reviewed. (39 refs.)

78-3609 **Mechanisms of Endonuclear Repair and Carcinogenesis.** (Ita) Santi, L. (Instituto Oncologia, Genova, Italy); Parodi, S. *Recent Prog Med (Roma)* 63(6): 571-591; 1977.

Studies of the carcinogenic and DNA-damaging effects of chemicals and radiation are reviewed. It is possible to predict the degree of correlation between the amount and type of DNA damage by a given compound and DNA repair and the carcinogenic potency of the compound. (33 refs.)

78-3610 **Occupational Cancer in Switzerland.** (Ger) Lamperth, E. (Tumbelenstrasse 58, 8330 Pfaffikon ZH, Switzerland). *Cancer Inf (Bern)* 12(2): 54-65; 1977.

Various occupational hazards associated with exposure to toxic chemicals in Switzerland are discussed, with emphasis on the problem of carcinogenesis. It is suggested that the risk of development of occupational cancer is significant in Switzerland. The control of occupational carcinogens in this country should be compulsory. (36 refs.)

78-3611 **Carcinogenic Hazards from Prenatal Exposure to Environmental Chemicals.** (Eng) Napalkov, N. P. (N. N. Petrov Res. Inst. Oncology, Leningrad, USSR). *In: Characterization and Treatment of Human Tumours 1977. Proceedings of the Seventh International Symposium on the Biological Characterization of Human Tumours Held in Budapest, 13-15 April, 1977.* Davis, W.; Harrap, K. R., eds. (Amsterdam: Excerpta Medica): Advances in Tumour Prevention, Detection and Characterization. Vol. 4, 332 pp.; 63-71; 1977.

A review of recent experimental data on transplacental carcinogenesis revealed the following: (1) a carcinogen (CG) administered during pregnancy may either kill the embryo or induce malformations and tumors in the offspring as a result of immediate action of the CG or its metabolites on fetal tissues; (2) reaction of the embryo to CG's depends on stage of embryonic development; tumor frequency is highest when exposure is during histogenesis; (3) in general, animals of a given species develop tumors of the same site and type following exposure to various CG's at different stages of embryogenesis; however, the teratogenic response of the embryo to CG's is determined by stage of embryogenesis rather than animal species or type of CG; (4) organ specificity of a CG does not invariably apply in transplacental carcinogenesis; (5) transplacentally induced congenital malformations and tumors represent independent consequences of the same cause and are not predetermined by the development of a congenital defect; (6) transplacental carcinogenesis may be due to endogenous synthesis of CG's in the mother; (7) transplancental exposure to CG's may heighten the susceptibility of an organism to the same or similar substance in postnatal life; (8) hormonal factors may influence the effect of transplacentally administered CG's significantly; (9) risk of tumor development depends on passage of a sufficient concentration of CG's or their active metabolites through the placental barrier and embryonal membranes; however, maternal organism is capable detoxifying transplacental CG's. (50 refs.)

78-3612 **Environmental Carcinogenesis: An Integrative Model.** (Eng) Trosko, J. E. (Dept. Human Development, Coll. Human Medicine, Michigan State Univ., E. Lansing, MI, 48824); Chang, C. C. *Q Rev Biol* 53(2): 115-141; 1978.

In this review, an integrative theory is proposed that attempts to organize the wealth of information on the phenomenon of environmental carcinogenesis. In this theory, environmental carcinogenesis is a process by which the genetic control of cell division and differentiation is altered by carcinogens, which include physical, chemical, and viral mutagens as well as chemical and viral gene modulators. Evidence seems to support the hypothesis that both mutations and epigenetic processes are components of carcinogenesis. The mutational basis of cancer is supported by the clonality of tumors; the mutagenicity of 90% of all tested carcinogens; the high mutation frequencies in humans having certain syndromes that predispose the individual to cancer; the correlation of in vitro DNA damage, mutagenesis, and transformation with in vivo carcinogenesis; age-related incidence of various hereditary tumors; and the correlation of photoreactivation of DNA damage and biological amelioration of UV-induced neoplasms. Since mutagens and gene modulators can be carcinogenic, carcinogens may affect the genes that control cell division. The proposed integrative theory is based on the mutation and epigenetic theories, the two-stage theory, and Coming's general theory of carcinogenesis. According to this theory, carcinogens affect regulatory genes that control a series of transforming genes. A general hypothesis is advanced that there is a common mechanism of somatic mutagenesis via error-prone repair of DNA damage linking carcinogenesis, teratogenesis, atherosclerosis, and aging. Concepts that provide a framework for evaluating the scientific, medical, and social implication of cancer are presented. (181 refs.)

78-3613 **Environmental Chemical Carcinogenesis.** (Eng) Stewart, B. W. (Sch. Pathology, Univ. New South Wales, Sydney, New South Wales, Australia); Sarfaty, G. A. *Med J Aust* 1(2): 92-95; 1978.

A carcinogen can be identified by large-population epidemiology, occupational epidemiology, chronic animal testing, short-term screening tests, and chemical analysis. Identification of a compound as a carcinogen in animals does not indicate that it is carcinogenic in humans, but is merely suggestive of the fact. Known human carcinogens should be regulated, but this is a social and economic problem as well as a biological and medical one. Certain personal habits still constitute the major established carcinogenic hazards for the general population. (14 refs.)

78-3614 **Air Pollution Research and Practice in East Germany.** (Ger) Dorre, W. H. (Lehrstuhl Allgemeine und Kommunale Hygiene des Hygiene-Instituts, Humboldt Universitat zu Berlin, Otto-Grotewohl-Strasse 1, DDR-108 Berlin, E. Germany); Grosser, P. J.; Hammje, K.; Knauer, A.; Theodor, H.; Wettig, K. *Z Gesamte Hyg* 24(1): 1-12; 1978.

Progress made during the last 15 yr in air pollution research in East Germany is reviewed. The medical aspects of air pollution are emphasized, and max permissible emission levels are tabulated for 143 industrial chemicals. (79 refs.)

78-3615 **Risks Caused by Low Levels of Pollution.** (Eng) Wilson, R. (Dept. Physics, Harvard Univ., Cambridge, MA, 02138). *Yale J Biol Med* 51(1): 37-51; 1978.

The theoretical and experimental evidence for the concept that pollutants in almost any concentration cause a small risk of death is reviewed. The hypothesis that cancer incidence is linear at low doses with applied dose of pollutant originated with radiation carcinogenesis. According to the linear theory, if the quantity of a carcinogen is constant and randomly distributed throughout the environment, the total number of cancers produced will be constant to within the square root of that number. Although there are various theoretical reasons for expecting to find a deviation from linearity, taking a linear dose-response relationship is recommended by most regulatory bodies. Data on cancers produced in humans by chemical carcinogens reveal few well-measured dose-response relationships, but there is a considerable amount of data on chemical cancers induced in animals. Many carcinogens such as vinyl chloride (VC) are indirect, and they only become carcinogenic as a result of the production of metabolites in the liver. The linearity of effect vs dose actually applies to the dose presented to the cell. The metabolic production of carcinogens in the liver might not be linear with the VC concentration. However, prudent public policy demands the assumption of linearity for exposure to the general public until further information is available. (50 refs.)

78-3616 **Complex Biological and Epidemiological Examinations to Recognize and Eliminate Occupational Health Risks Posed by Air Pollution.** (Ger) Haublein, H. G. (Zentralinstitut fur Arbeitsmedizin der DDR, Noldnerstrasse 40-42, DDR-1134 Berlin, E. Germany); Blau, F
Konetzke, G.; Schneider, W. D.; Thiele, H. *Z Gesamte H*
24(4): 248-252; 1978.

Respiratory tract diseases caused by air pollution accounte
for 11.49% of all occupational diseases in East Germany du
ing 1970-1976. The incidence of silicosis declined markedl
but that of asbestosis, including its pleural forms, remaine
constant. Increases in the incidence of bronchial cance
chronic unspecified lung diseases, and respiratory tract alle
gies are attributed to improved registration procedures. C
the total number of occupational diseases, 3.42% represente
chronic intoxication caused by the inhalation of chemica
such as carbon monoxide, halogenated hydrocarbons, ben
zene and its nitro and amino derivatives, and carbon disu
fide. Metals, metallic compounds, and pesticides are no long
er a leading cause of occupational intoxication. Th
frequency of intoxication due to inhalation of different type
of dust may be underrepresented, considering the large num
ber of exposed workers. The effectiveness of preventive indus
trial medicine programs and of the early registration of occu
pational diseases was reflected in an epidemiologic study o
$>$ 15,000 workers. A study covering 300,000 workers fron
1976 to 1978 is now in progress. (28 refs.)

78-3617 **Carcinogenesis Induced by Trace Contaminant
in Potable Water.** (Eng) Kraybill, H. F. (Di
of Cancer Cause and Prevention, NCI, Bethesda, MD). *Bu*
Ny Acad Med 54(4): 413-427; 1978.

The following are some recognized and suspect carcinogen
in US drinking water and their concentrations (in μg/lite
when given): aldrin (5.4), benzene (50), benzo(a)pyren
(0.0002-0.002), bis(2-chloroethyl)ether (0.42), lindane, ca
bon tetrachloride (2.0-3.0), chlordane (0.1), chlorofor
(0.1-311), 1,2-dibromoethane, dieldrin (8.0), dichlorod
phenyltrichloroethane (DDT), dichlorodiphenyldichlor
ethylene (DDE) (0.05), 1,4-dioxane (1.0), endrin (0.004), he
tachlor, trichloroethylene, and vinyl chloride (10.0). Of the
compounds, benzo(a)pyrene and vinyl chloride are the on
recognized carcinogens. Only volatile organic compoun
have been identified in US drinking water, and a much larg
component of nonvolatile substances remains to be identifi
or quantified. In city water in the Netherlands and German
concentration ranges of inorganic contaminants such as ars
nic, cadmium, chromium, and selenium are 1.0-8.1, 2.0-9.
4.5-10.0, and 3.1-6.0 μg/liter, respectively. Asbestifor
materials or asbestos particles have been found in many riv
systems at concentrations $>$ 10 μg/gallon. In a study of ca
cer mortality in 10 river basins in the US, nickel concentr
tions appeared to correspond with oral and intestinal canc
death rates, arsenic with cancer of the eye and larynx a
myeloid leukemia. Beryllium correlated with bone cancer a
with mortalities from breast and uterine cancer. Lead w
associated with leukemia and lymphoma and with kidne
stomach, intestinal, and ovarian cancer. The results of va
ous epidemiological studies throughout the US are reporte

The need for in vitro bioassays to augment in vivo procedures in determining carcinogenicity is stressed. (30 refs.)

78-3618 **Personal Habits.** (Eng) Wynder, E. L. (American Health Foundation, 1370 Ave. Americas, New York, NY, 10019). *Bull NY Acad Med* 54(4): 397-412; 1978.

A review of the association between various personal habits and cancer is presented. Among the relationships discussed are the following: tobacco smoking and lung cancer; alcohol intake and cancer of the mouth, esophagus, and larynx; iodine deficiency and cancer of the thyroid; atrophic gastritis and stomach cancer; and fat intake and colon and breast cancer. (8 refs.)

78-3619 **Tumor Promoters: Carcinogenesis Gets More Complicated.** (Eng) Marx, J. L. (No affiliation given.). *Science* 201(4355): 515-518; 1978.

Promotion is important in the development of several cancers in a variety of species, and many carcinogens may have the ability to both initiate and promote tumor formation. The initiation step is irreversible, but if exposure to promoter is stopped before the cells gain the ability to multiply in the absence of the promoter, tumor formation may be avoided. Among the chemicals with promoting activity are the phorbol esters; phenobarbital, which appears to promote liver tumors; saccharin and sodium cyclamate, which appear to promote bladder tumors; bile acids, which promote the development of colon cancer; and cigarette smoke. Most investigators think that initiation involves an alteration in the cell's DNA by the initiating agent. Tumor promoters appear to interfere with the normal development of cells. All promoters tested increased cellular ornithine decarboxylase activity, which may be a prerequisite for promotion. Proteases are also implicated in this respect. It is possible that promoters bind to a receptor for a naturally occurring material, namely, epidermal growth factor (EGF), which stimulates the division of epidermal cells. There may be several stages in the progression of initiated cells to benign and then to malignant tumors. Since the effects of promotion are reversible, it may be possible to use inhibitors to prevent cancers from developing. (no refs.)

78-3620 **Diethylstilbestrol: A Review of Its Toxicity and Use as a Growth Promotant in Food-producing Animals.** (Eng) McMartin, K. E. (Toxicology Center, Dept. Pharmacology, Univ. Iowa, Iowa City, IA, 52242); Kennedy, K. A.; Greenspan, P.; Alam, S. N.; Greiner, P.; Yam, J. *J Environ Pathol Toxicol* 1(3): 279-313; 1978.

The human and animal uses and effects of diethylstilbestrol (DES) are reviewed. In humans, DES has been used to prevent abortion, prevent implantation, replace estrogens, and treat prostatic cancer. However, it has induced neoplastic and nonneoplastic reproductive tract disorders in the female offspring of mothers treated during pregnancy and, possibly, endometrial carcinoma in women taking the compound. DES is also used a a growth promotor in livestock. It is estimated that DES residues in meat are at most 20% of the harmful effect dose. If the proper regulations are followed, there should be no danger to humans from this source. (162 refs.)

78-3621 **Food Policy and Health.** (Eng) Whitehead, R. G. (MRC Dunn Nutrition Unit, Cambridge, England). *J Royal Soc Arts* 76(5265): 552-563; 1978.

The role of proper nutrition in the maintenance of good health is discussed. One study indicated that an increase in carbohydrate intake to 55%-60% of the total energy intake will help prevent bowel cancer, that reducing fat intake from 40% to 30% of the total energy intake will help prevent breast and colon cancer, and that reducing salt consumption to 3 g/day will help prevent stomach cancer. (9 refs.)

78-3622 **The Chemistry and Toxicology of Hair Dyes.** (Eng) Burnett, C. M. (Clairol Res. Lab., Stamford, CT); Corbett, J. F. *In: Cutaneous Toxicity.* Drill, V. A.; Lazar, P., eds. (New York: Academic Press, Inc.): 277 pp.; 203-221; 1977.

Data on the toxicity and carcinogenicity of hair dye preparations are reviewed. Most of the current data are based on animal tests, which show no carcinogenic effects, and retrospective surveys, which show no evidence of increased cancer incidence that can be correlated with hair dye usage. Several in vitro screening tests have indicated that components of these dyes are mutagenic, but a correlation between this mutagenicity and human toxicity and carcinogenicity has yet to be proved. (47 refs.)

78-3623 **Beryllium: Carcinogenicity Studies (Letter to Editor).** (Eng) Wagoner, J. K. (Dept. Labor, Office Assistant Secretary, Occupational Safety and Health Adim., Washington, DC, 20210); Infante, P. F.; Mancuso, T. *Science* 201(4353): 298-303; 1978.

A previous article in which concern was expressed about fair play in the conduct of epidemiological studies and government regulations of beryllium (Be) is criticized. The authors, as government and independent researchers, accepted responsibility for the objective conduct and evaluation of these studies and they note that there is continued reluctance of industry and its consultants to accept the carcinogenicity of Be. According to several epidemiological studies, there is an increased risk of lung cancer mortality (LCM) among occupationally exposed subjects. One study by the National Institute for Occupational Safety and Health (NIOSH) found an excess of LCM in a subcohort of individuals entered in the US Beryllium Case Registry with a diagnosis of prior Be-related pneumonitis or bronchitis. The individuals had short-term exposure to Be. These studies are consistent with numerous animal bioassay studies demonstrating that Be is carcinogenic by several routes and in many species and, specifically, with animal bioassay results demonstrating lung cancer induction in 51% of exposed animals by a single dose of Be oxide. A Be exposure limit of 2 $\mu g/m^3$ set 30 yr ago by the government is still not being adhered to by industry, and in several operations levels have exceeded 1,000 $\mu g/m^3$. Industry consultants claim that the NIOSH study failed to exhibit a dose-response relation, as measured by duration of employment of LCM. However, individuals exposed to high concentrations over a short period could have a total lung Be burden as great or greater than that of individuals exposed over a long period to lower concentrations. this is supported by the fact that the body does not clear Be readily. In addition, the NIOSH study provides no data to refute a dose-response relation. (26 refs.)

78-3624 **Toxicological Effects of Cadmium.** (Eng) Lauwerys, R. (No affiliation given). *In: Criteria (Dose/Effect Relationships) for Cadmium. Report of a Working Group of Experts prepared for the Commission of the European Communites, Directorate-General for Social Affairs, Health and Safety Directorate.* (New York: Pergamon Press): 202 pp.: 67-116; 1978.

The potential hazards to humans resulting from short- and long-term exposure to cadmium are reviewed. Short-term ingestion primarily affects the gastrointestinal tract, and short-term inhalation primarily affects the lungs. Toxic effects on the cardiovascular system, testis, liver, kidney, and nervous system have also been demonstrated in animals. The two main target organs after long-term exposure to moderate Cd concentrations are the lungs and kidneys, but the bones and hematopoietic system can also be affected. In animals, effects on the cardiovascular system, liver, growth, and survival have been demonstrated. Cd induces cancer in animals, primarily at the site of injection. Some surveys among occupationally exposed subjects suggest that Cd may also be carcinogenic in humans, but the evidence is inconclusive. There is no indication that nonoccupational exposure to Cd constitutes a carcinogenic hazard. There are conflicting reports in the literature concerning the mutagenic action of Cd compounds. The effects of Cd on the reproductive processes (fertility, embryotoxicity, and perinatology) of animals are discussed. (no refs.)

78-3625 **An Assessment of Experimental Carcinogen-Detecting Systems with Special Reference to Inorganic Arsenicals.** (Eng) Wildenberg, J. (Dept. Epidemiology and Statistics, American Cancer Society, 777 Third Ave., New York, NY, 10017). *Environ Res* 16(1/3): 139-152; 1978.

Human, animal, and short-term carcinogenicity data for arsenical compounds are reviewed and assessed. Epidemiologic and clinical observations indicate a causal relation between inorganic arsenic and skin cancer, and they suggest that arsenicals may also be respiratory carcinogens. However, a carcinogenic role for inorganic arsenic has not been demonstrated in animal experiments, nor have positive findings with arsenicals been reported in short-term tests. Some limitations in the short- and long-term bioassay systems that are used to identify potential human carcinogens are discussed. It is recommended that mutation induction in *Salmonella* be adopted as a prescreen for certain classes of chemicals. Additional prescreen assays, independent of mutagenicity, should be developed and validated to supplement the bacterial results. (50 refs.)

78-3626 **Cancer in the Workplace--Percivall Pott to the Present.** (Eng) Cowles, S. R. (Occupational Medicine Branch, Naval Regional Medical Center, Bremerton, WA, 98314). *Milit Med* 143(6): 395-400; 1978.

Known and suspected carcinogens commonly found at Naval installations, particularly shipyards, are reviewed, and methods of controlling human exposure to these substances are outlined. The carcinogens include physical agents (cigarettes, asbestos), metals (Ni, As), and hydrocarbons (ethylenethiourea, 4,4′-methylenebis(2-chloroaniline), vinyl chloride, and polychlorinated biphenyls). (15 refs.)

78-3627 **The Significance of Vinyl Chloride as a Pollutant from the Viewpoint of Industrial Medicine, Experimental Oncology, and Industrial Toxicology.** (Ger) Konetzke, G. (Zentralinstitut fur Arbeitsmedizin der DDR, Noldnerstrasse 40-42, DDR-1134 Berlin, E. Germany); Bittersohl, G.; Grund, W.; Schramm, T.; Teichmann, B.; Zschunke, E. *Z Gesamte Hyg* 24(7): 501-508; 1978.

The carcinogenic effect of vinyl chloride (VC) and its polymers, recommendations for the protection of workers exposed to VC, and the industrial exposure of workers in East Germany to VC are reviewed. In rats, mice, hamsters, and rabbits, inhalation of 50-10,000 ppm VC monomer (VCM) induced tumors. Even low doses (50 ppm for 4 hr/day, 5x/wk, for 1 yr) produced hepatic angiosarcomas and nephroblastomas. Hemangioepitheliomas of the liver have been associated with exposure of humans to VCM. Brain, lung, blood, and lymph malignancies are also associated with VCM. However, no such cases have yet been found in East Germany. A list of clinical and x-ray studies for monitoring workers exposed to VC is presented. Several countries have decreased the standard levels of VC allowable in workplaces because of accumulating evidence that workers were being exposed to harmful levels. (41 refs.)

78-3628 **N-Nitrosomorpholine.** (Eng) IARC Working Group (Lyon, France). *In: Some N-Nitroso Compounds.* Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 263-280; 1978.

An evaluation of the carcinogenic effect of N-nitrosomorpholine (NMOR) is presented, NMOR was found in 3/11 batches of analytical grade dichloromethane at levels of 10-32 μg/liter and in 4/10 batches of analytical grade chloroform at levels of 2-376 μg/liter. Carcinogenicity studies have been conducted in mice, rats, hamsters, and zebra fish. The carcinogenicity of precursors, derivatives, and factors that modify carcinogenicity in animals have also been investigated. After po administration, NMOR produced benign and malignant tumors of the liver and lung in mice; the liver, kidney, and blood vessels in rats; and the liver in hamsters. After sc administration, of single and multiple doses, hamsters developed tumors of the digestive and respiratory tracts. After iv injection, rats developed liver tumors. When NMOR was added to their tank water, zebra fish developed liver tumors. A dose-response relationship was determined. NMOR was mutagenic in several bacterial strains, Chinese hamster V79 cells, in a host-mediated assay with mice, and in Drosophila. No human data are available. However, NMOR should be regarded for practical purposes as if it were carcinogenic to humans. (57 refs.)

78-3629 **N-Nitrososarcosine.** (Eng) IARC Working Group (Lyon, France). *In: Some N-Nitroso Compounds.* Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 327-335; 1978.

Studies on the carcinogenicity of N-nitrososarcosine (NSAR) are evaluated relative to a possible carcinogenic risk to humans. NSAR has been found in some meat samples. It produced squamous cell carcinomas of the nasal cavities in mice and esophageal carcinomas in rats after its po administration. After ip injection, it produced liver cell carcinomas in newborn mice. Rats exposed to NSAR ethyl ester developed esophageal carcinomas. NSAR (1 g/kg body wt) administered to mice by gavage was not mutagenic in the host-mediated assay. The general population may be exposed to low levels of NSAR, but no epidemiological data or case reports were available. There is sufficient evidence of a carcinogenic effect of NSAR in two experimental animal species, and therefore it should be regarded as if it were carcinogenic to humans. (24 refs.)

78-3630 **N′-Nitrosonornicotine.** (Eng) IARC Working Group (Lyon, France). *In: Some N-Nitroso Compounds.* Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 281-286; 1978.

Biological data relevant to the evaluation of a carcinogenic risk of N′-nitrosonornicotine (NNN) to humans are presented. NNN has been found in cigarette smoke and in various tobaccos. It has been shown to be carcinogenic in rats, mice, and Syrian golden hamsters. After po administration to 20 rats (total dose, 630 mg/animal), 12 surviving rats developed esophageal tumors (11 papillomas, 3 carcinomas) plus 1 pharyngeal papilloma and 3 carcinomas of the nasal cavity with brain invasion. Of 20 Syrian hamsters given sc injections of NNN (Total dose, 375 mg/animal) 12 developed single papillary tumors of the trachea within 83 wk, and 1 had an adenocarcinoma of the nasal cavity. Of 40 mice injected ip with 0.1 ml NNN once a wk for 41 wk, 25 died within 7 mo with no evidence of tumors, but 7/8 animals that died after 8 mo had multiple pulmonary adenomas. No human data are available; however, tobacco smokers are exposed to NNN along with other N-nitroso compounds. For practical purposes, NNN should be regarded as if it were carcinogenic to humans. (13 refs.)

78-3631 **N-Nitrosopyrrolidine.** (Eng) IARC Working Group (Lyon, France). *In: Some N-Nitroso Compounds.* Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 313-326; 1978.

Data on the carcinogenicity of N-nitrosopyrrolidine (NPYR), a compound formed during the heating of N-nitrosoproline, are presented. NPYR has been found in the vapor produced during the frying of bacon, tobacco smoke, waste water from chemical factories, grilled and fried bacon, dry premixed cures containing spices and sodium nitrite, animal feed, and cured lunchmeats, ham, and sausage. Of 40 mice given NPYR po (total dose, 0.015 g/mouse), 4/34 surviving animals had 51 lung adenomas. Of 25 BD rats given 5 or 10 mg/kg/day in the drinking water for 150 days and then double these doses, 23/25 animals developed hepatocellular carcinomas after an av induction time of 470 and 290 days, respectively (av total doses causing tumors in 50% of rats, 3.9 or 4.2 g/kg). In other rat species, hepatocellular carcinomas, papillary mesotheliomas of the tunica vaginalis, interstitial cell tumors, a cavernous hemangioma of the testes, cholangiocarcinomas, and olfactory carcinomas were observed. In Syrian golden hamsters, sc administration of NYPR induced lung tumors. A dose-response relationship was established in rats. NPYR produced reverse mutations in *Escherichia coli* and *Salmonella typhimurium* and 8-azaguanine-resistant mutants in Chinese hamster V79 cells. Although human data are available, there is sufficient evidence of a carcinogenic effect in rats for NPYR to be regarded as if it were carcinogenic to humans. (51 refs.)

78-3632 **N-Nitrosomethylethylamine.** (Eng) IARC Working Group (Lyon, France). *In: Some N-Nitroso Compounds.* Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 221-226; 1978.

The carcinogenicity of N-nitrosomethylethylamine (NMEA) was evaluated on the basis of current biological data. NMEA occurs in tobacco smoke condensate and in various meats and meat products. Of a group of 15 female BD rats given NMEA in the drinking water at doses at 1 or 2 mg/kg/day, 9 developed hepatocellular carcinomas and 1 a fibrosarcoma of the vagina. The av induction time was 500 to 360 days for the two dosage groups, respectively, and the av total doses to induce tumors in 50% of the animals was 0.42 and 0.75 g/kg. Human data are not available; however, reports suggest that tobacco smokers may be exposed to NMEA along with other N-nitroso compounds. The experimental evidence is sufficient for NMEA to be regarded as if it were carcinogenic to humans. (15 refs.)

78-3633 **N-Nitrosopiperidine.** (Eng) IARC Working Group (Lyon, France). *In: Some N-Nitroso Compounds.* Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 287-301; 1978.

An evaluation of the carcinogenic risk of N-nitrosopiperidine (NPIP) to humans is presented. NPIP has been found in tobacco smoke, wastewater from chemical factories, cheeses, smoked codfish, various processed and preserved meats, dry, premixed cures containing spices and sodium nitrite and animal feed. In mice, NPIP causes benign and malignant tumors of the liver, lung, forestomach, and esophagus. In rats, NPIP causes tumors of the liver, esophagus, and respiratory system. In addition, it produces tumors of the upper digestive tract, respiratory system, and liver in hamsters and hepatocellular carcinomas in monkeys. Single doses of NPIP are carcinogenic in mice and hamsters. No case reports or human epidemiological data are available. Since the general population may be exposed sporadically to low levels of NPIP and since the animal evidence is conclusive, NPIP should be regarded for practical purposes as if it were carcinogenic to humans. (59 refs.)

78-3634 **N-Nitrosoproline and N-Nitrosohydroxyproline.** (Eng) IARC Working Group (Lyon, France). *In: Some N-Nitroso Compounds.* Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland) IARC Monographs on the Evaluation of the Carcinogeni Risk of Chemicals to Humans. Vol. 17, 365 pp.; 303-311 1978.

An evaluation of the carcinogenic effect of N-nitrosoprolin (NPRO) and N-nitrosohydroxyproline (NHPRO) is presented. Chemical and physical data and the production, use, occurrence, and analyses of these compounds are reviewed NPRO has been found in uncooked cured meat products NHPRO was found in one meatloaf sample. When mice wer given 325 or 650 mg/mouse in the drinking water, the incidence of lung adenomas was not greater than that of controls When rats were given NPRO or NHPRO in drinking wate at a concentration of 0.015% for 75 wk, no significant differences in tumor incidence were observed between untreate and treated animals. No carcinogenic effects were observe in rats given NPRO or NHPRO intragastrically once a w for 4 wk (total dose: 19 or 38 g/kg body wt, respectively) No human data are available. Although the general population may be exposed to low levels of NPRO and NHPRO the data are insufficient for an evaluation of the carcinogenicity of NPRO or NHPRO. (51 refs.)

78-3635 **N-Nitrosomethylvinylamine.** (Eng) IAR Working Group (Lyon, France). *In: Som N-Nitroso Compounds.* Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IAR Monographs on the Evaluation of the Carcinogenic Risk o Chemicals to Humans. Vol. 17, 365 pp.; 257-261; 1978.

The carcinogenic risk of N-nitrosomethylvinylamin (NMVA) was evaluated. NMVA is carcinogenic in rats, th only species tested. Of a group of 19 rats given 0.3 or 0. mg/kg/day in the drinking water, papillomas developed i 2 and nodular and widely distributed squamous cell carcinomas of the esophagus in 17. In addition, 4 had carcinomas of the tongue, 5 had carcinomas of the pharynx, an 8 had bile duct proliferation and hepatic cysts. Inhalatio and/or intratracheal administration of NMVA (single dos of 18 mg/kg, or 25 or 50 ppm in air 2x/wk for 30 min produced carcinomas of the nasal cavities. Although ther are no human data on the carcinogenic effect of NMVA, th experimental evidence indicates that for practical purpose it should be regarded as if it were carcinogenic to humans (11 refs.)

78-3636 **Toxicity of Inhalation Anaesthetic Agents** (Eng) Cohen, E. N. (Dept. Anesthesiology Stanford Univ. Medical Center, Stanford, CA, 94305). *Br Anaesth* 50(7): 665-675; 1978.

The relationship between anesthetic metabolism and toxicity the mechanisms of anesthetic toxicity, and specific organ toxicity of anesthetic agents are reviewed. Evidence for the direc induction of human cancer by anesthetic drugs is largely epidemiologic. Studies have indicated that there is an increased incidence of cancer (threefold increase in leukemia and lymphoma) in women exposed to waste gases; no similar increase has been observed for men. There is some evidence that nitrous oxide is metabolized. (82 refs.)

78-3637 **Animal Models: Diet and Large Bowel Cancer.** (Fre) Martin, M. S. (Laboratoire d' Immunologie, Faculte de Medecine, INSERM, U-45, boulevard Jeanne-d'Arc, F21033 Dijon, France). *Bull Cancer (Paris)* 65(1): 49-52; 1978.

Literature reports on the effect of various dietary factors on chemically induced cancer of the intestine in the rat are reviewed. The cancers were induced by direct intrarectal instillation of N-methyl-N'-nitro-N-nitrosoguanidine methylnitrosourea, or methylazoxymethanol or by feeding the rats 1,2-dimethylhydrazine or azoxymethane. The factors studied included fat level of diet, quality and quantity of fat, fecal excretion of neutral and acid steroids, intestinal microflora, and fiber content of the diet. Both animal and vegetable fats potentiated the effects of the carcinogens. Bacterial flora appeared to play a fundmental role in the metabolism of certain carcinogens. The bacterial enzyme converted noncarcinogens into carcinogens. A diet high in beef increases the number of intestinal bacterial flora and, thus, would indirectly contribute to increased levels of carcinogens. There did not appear to be any correlation between dietary fiber and carcinogenesis in the rat animal model. (13 refs.)

78-3638 **Phenacetin Abuse: A Review.** (Eng) Carro-Ciampi, G. (Laboratorio di Farmacologia, Istituto Superiore di Sanita, 00161 Rome, Italy). *Toxicology* 10(4): 311-339; 1978.

Excessive and prolonged consumption of phenacetin-containing analgesics is associated with one or more of the following: hemolytic anemia with methemoglobinemia and sulfhemoglobinemia, impaired renal function with renal papillary necrosis and pyelonephritis, and uroepithelial cancer of the renal pelvis and lower urinary tract. A working hypothesis might be that the three groups of conditions are successive stages of a progressive disease. (168 refs.)

78-3639 **Carcinogenic Activity of Antitumor Chemotherapeutic Agents.** (Ita) Cardinali, G. (Oncologia Clinica, Universita degli Studi, Centro Oncologico, Ancona, Italy); Scoponi, C.; Trivisonne, R. *Recent Prog Med (Roma)* 63(6): 649-668; 1977.

Studies of the carcinogenicity of various anticancer agents are reviewed. The anticancer drugs mechlorethamine, cyclophosphamide, isophosphamide, chlorambucil, melphalan, chloronaphazine, busulfan, urethane, nitrosourea, triethylenemelamine, triethylenetriphosphoramide, uracil mustard, dibromomannitol, dibromodulcitol, actinomycin D, adriamycin, daunomycin, mitomycin C, streptozotocin, 6-mercaptopurine, methotrexate, azathioprine, procarbazine, and dimethyltriazenoimidazole carboxamide have carcinogenic activity. (123 refs.)

78-3640 **Streptozotocin.** (Eng) IARC Working Group (Lyon, France). *In: Some N-Nitroso Compounds.* Magee, P. N., Chairman (International Agency for Research on Cancer: Switzerland): IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Vol. 17, 365 pp.; 337-349; 1978.

Carcinogenicity data for streptozotocin (STR), an antitumor drug, were evaluated to determine its risk to humans. STR is produced by the soil microorganism *Streptomyces achromogenes.* It is carcinogenic in mice, rats, Syrian golden hamsters, and Chinese hamsters following iv or ip injection. STR produces benign and malignant tumors of the liver and kidney and islet cell tumors of the pancreas. It is carcinogenic after administration in single doses. STR was shown to be mutagenic in *Salmonella typhimurium* and *Drosophila melanogaster* and in host-mediated assays in rats and mice. It has been used to treat pancreatic islet-cell tumors and malignant carcinoid tumors in humans. Side effects included nausea and vomiting, renal and hepatic toxicity, bone marrow damage, anemia, leukopenia, and thrombocytopenia. Although no epidemiological data were available, there is sufficient evidence of a carcinogenic effect of STR in several animal species, and it should be regarded as if it were carcinogenic to humans. (38 refs.)

78-3641 **The Mycotoxins and Human Health Hazards.** (Eng) Linsell, C. A. (International Agency Res. Cancer, 150, Cours Albert-Thomas, 69008 Lyon, France). *Ann Nutr Aliment* 31(4/5/6): 997-1004; 1977.

The role of mycotoxins in human disease is reviewed briefly. Among the various mycotoxins, aflatoxins have been shown to be the most potent hepatocarcinogens. This mycotoxin is present in human foodstuffs in areas of the world where liver cancer is commonly reported. It is suggested that the toxicity of mycotoxins may only be the tip of the iceberg and that more pathologies may develop with time. (31 refs.)

78-3642 **The Public Health Significance of Mycotoxins.** (Eng) Rutledge, A. E. (Microbiological Labs., Div. Agrimerica, Inc., 1829 Stanley St., Northbrook, IL, 60062). *Ann Nutr Aliment* 31(4/5/6): 1019-1030; 1978.

A review of literature data on the toxicity of the major mycotoxin-producing fungi is presented. Special attention is focused on contamination by aflatoxins, stachybotrys toxins, penicillium toxins, rubratoxins, ochratoxins, and various pulmonary toxins. Studies of aflatoxins indicate that the reticuloendothelial system is impaired seriously during aflatoxicosis. (30 refs.)

78-3643 **Carcinogens in Food.** (Fre) Griciute, L. (Centre International de Recherche sur le Cancer, 150, cour Albert-Thomas, F69372 Lyon Cedex 2, France). *Bull Cancer (Paris)* 65(1): 53-58; 1978.

A review of research linking human cancer to the intake of chemicals shows that a definite relationship has been established only for aflatoxin and primary liver cancer. However,a number of chemicals that are carcinogenic to animals, such as polycyclic aromatic hydrocarbons and N-nitroso compounds, are present in human food. Research has shown that the av intake of benzo(a)pyrene (BP) in East Germans is 24-85 mg over a life-span of 70 yr and that most of this BP is from bread, margarine, vegetable oil, and beans. Nitrosamines are converted in vivo from nitrates in food and from the nitrites used for curing meat. An attempt has been made to correlate the intake of N-nitroso compounds, aromatic hydrocarbons, and aflatoxin with the incidence of esophageal cancer in Iran. BP contamination of apple cider has been studied in Brittany, another area with a high incidence of esophageal cancer. (27 refs.)

78-3644 **A Review of the Literature of Rotenone 1,2,12,12a-Tetrahydro-8,9-dimethoxy-2(1-methylethenyl)-1-benzopyrano- [3,5-b]furo[2,3-h][1]benzopyran-6(6h)-one.** (Eng) Haley, T. J. (Dept. Health, Education and Welfare, Food and Drug Administration, Natl. Center Toxicological Res., Jefferson, AR, 72079). *J Environ Pathol Toxicol* 1(3): 315-337; 1978.

The chemistry, biotransformation, pharmacology, toxicology, and carcinogenicity of rotenone (1,2,12,12a-tetrahydro-8,9-dimethoxy-2-(1-methylethenyl)--1-benzopyrano- [3,5-b]furo[2,3-h][1]benzopyran-6(6h)-one are reviewed. Further studies with low doses of rotenone are necessary to determine the exact carcinogenic risk, and epidemiological studies with exposed workers are necessary to determine the risk to humans. (194 refs.)

78-3645 **Mechanisms of Ethionine Carcinogenesis.** (Eng) Sharma, O. K. (Dept. Microbiology, Univ. Colorado Medical Center, Denver, CO, 80262); Kuchino, Y.; Borek, E. *Adv Enzyme Regul* 16: 391-405; 1978.

Recent laboratory findings on the mechanisms of ethionine (Eth) carcinogenesis are reviewed. Acute exposure of rats to Eth induces a rapid decrease in hepatic ATP concentration followed by an inhibition of RNA and protein synthesis. There is a specific inhibition of ribosomal RNA synthesis. Cellular ATP is depleted because of an accumulation of S-adenosylethionine. These effects can be completely reversed by replenishing the cells with ATP precursors. In studies of chicks treated with Eth and adenine (Ade), induction of ovalbumin and conalbumin synthesis was not observed in the primitive oviduct of 5- to 6-wk-old chicks that had not received primary stimulation with estrogen. This suggests that Eth alone cannot cause cytodifferentiation and growth of the primitive oviduct, but that in tissues differentiated by the action of estradiol, it can induce specific protein synthesis. The elevation of progesterone levels upon administration of Eth and Ade may produce other hormonal imbalances and thus have implications in the mechanisms of carcinogenesis. Studies using transfer RNA (tRNA) isolated from the livers of rats injected with (ethyl-^{3}H)-Eth revealed that about 50% of the label was eluted with the lysine tRNA as the last peak. Rat liver tRNA-Lys has at least two isoreceptors; Eth preferentially alkylated tRNA$_2$-Lys. Whether the alkylation of tRNA by carcinogens plays a role in the onset of neoplasia is unknown. (76 refs.)

78-3646 **Pathological and Toxicological Data on Chlorinated Pesticides and Phenobarbital.** (Eng) Butler, W. H. (Dept. Histopathology, Saint George's Hosp. Medical Sch., Blackshaw Road, London SW17 0QT, England); Jones, G. *Ecotoxicology and Environmental Safety* 1(4): 503-509; 1978.

Data on the carcinogenicity of the organochlorine pesticides DDT (1,1,1-trichloro-2,2-bis(p-chlorophenyl)ethane), dieldrin, mirex, heptachlor, chlordane, and Aramite [sulfurous acid 2-(p-tert-butylphenoxy)-1-methylethyl 2-chloroethyl ester] in mice and rats are reported, along with current studies of phenobarbital. Aramite produced 2 hepatocellular carcinomas in a group of 21 FDRL Wistar rats receiving 1,580 ppm. Lower doses resulted in a low incidence of liver carcinomas and hyperplastic nodules in these rats, hyperplasia only in CFN rats, and neither hyperplasia nor neoplasia in Sprague-Dawley rats. However, these lower doses induced adenocarcinomas of the gallbladder and extrahepatic biliary ducts in dogs. Most of the chlorinated pesticides have been studied in mice, and on the basis of available data, it cannot be concluded that these compounds are carcinogenic for the mouse liver. When male C3H mice were fed 1,000 ppm PB, a 70%-80% incidence of hepatic nodules was seen at about 80 wk, but it was uncertain whether these lesions were carcinoma. Although the histological assessment is incomplete, hepatocellular carcinoma was not seen during a 2-yr study of feeding 1,000 ppm PB to male Fischer rats. Except possibly for Aramite, there are little reliable data as to the carcinogenicity of organochlorine pesticides or PB in other species. If this assessment of the available toxicological and pathological data is correct, it is not likely that these compounds represent a high carcinogenic risk for humans. (19 refs.)

78-3647 **On the Mechanism and Genetic Control of Mutagenesis Induced by Carcinogenic Mutagens.** (Eng) Radman, M. (Deparatement de Biologie Moleculaire, Universite Libre de Bruxelles, B-1640 Rhode St. Genese, Belgium); Villani, G.; Boiteux, S.; Defais, M.; Caillet-Fauquet, P.; Spadari, S. *In: Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 903-922; 1977.

Experiments on the mechanisms of mutagenesis induced by carcinogensare reviewed. Studies using the radioactive phage πX174 and its single- and double-stranded DNA's indicated that the first pyrimidine dimer encountered by DNA polymerase blocked DNA replication in intact host cells. UV irradiation of the host cell induced an increased capacity to copy damaged DNA. This could be a result of the induction of new DNA polymerases, inhibition of the proofreading activity of constitutive DNA polymerases, or modification of the DNA. No evidence has been found for the induction of any new DNA polymerase. Beryllium, which has been shown to inhibit the proofreading $3' \to 5'$ exonuclease activity of the *Micrococcus luteus* DNA polymerase and to decrease the fidelity of avian myeloblastosis virus reverse transcriptase, caused infidelity of in vitro DNA synthesis by HeLa α, β, and γ DNA polymerases. UV irradiation of the template synergistically increased infidelity in the presence of Be^{++}. A synthetic protease inhibitor, tosylleucylchloromethyl ketone, inhibited UV-induced mutagenesis and prophage induction in *Escherichia coli* at concentrations that were not toxic for intact *E. coli* and that did not prevent induction at 42 C of a temperature-inducible prophage whose repressor is inactive at 42 C. It appears that the decisive inducing event is proteolytic cleavage of genetic repressors. It is proposed that three major factors are necessary for extensive mutagenesis: unrepaired DNA lesions, error-prone DNA synthesis (SOS induction), and cellular proliferation. (48 refs.)

78-3648 **Active Carcinogenesis and DNA Repair.** (Ita) Sbano, E. (Siena, Italy). *G Ital Dermatol* 113(1-2): 63-78; 1978.

Recent findings suggest correlations between defects in the repair of actinic DNA damage and actinic carcinogenesis. The mechanism of cancer induction by altered DNA repair is not known. (86 refs.)

78-3649 **DNA Repair: New Clues to Carcinogenesis.** (Eng) Marx, J. L. (No affiliation given). *Science* 200(4341): 518-521; 1978.
